How Britain runs its Science How the US runs its Science

These two new Nature wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from Nature's offices in Basingstoke and New York.

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

Ortho offers unexcelled systems for immunobiology researchers

OKT3 POSITIVE

LYMPHOCYTES

MONOCYTES

Three major subpopulations of white cells by forward and 90° light scatter measurements of whole blood (RBC lysis only). Using Ortho-mune Monoclonal Antibodies, gating on the lymphocyte population, human peripheral T lymphocytes (OKT3* cells) can be quantitated and/or sorted.

Ortho Diagnostic Systems has established a firm leadership position in cell sorting and analysis instrumentation—in fact, acceptance of Ortho systems by the scientific community has been so great that these instruments now are considered the standard of performance in the field.

Versatile Instrumentation

The Ortho Cytofluorograf*

Flow Cytometer is an example of that leadership and commitment to research. As the only flow cytometer to offer a choice of five lasers, (including two installed as standard), the Cytofluorograf provides exceptional applications flexibility.

Green Fluorescence

Ortho

March 2019

Ortho

March 2019

March 2019

March 2019

Ortho

March 2019

Flexibility is enhanced further by a modular design which allows the system to be upgraded as research needs change. Performance too is outstanding with analysis rates of up to 10,000 cells per second. And only Cytofluorograf offers direct measurement of seven optical parameters including axial light loss, a valuable technique that allows the use of non-fluorescent stains.

The new 2150 Computer and software can acquire up to 16 histograms and simultaneously display any four of these, all in real-time, allowing the operator complete control over all aspects of the experiment. Because 2150 has two independent microprocessors,

it can perform rapid
multiparameter sort
decisions while simultaneously providing complete
statistical data analysis. This
capability provides significantly
higher throughput and increased
sorting efficiency.

Wide Applicability

The system has proved extremely valuable in cell-antigen and tumor studies. It can also be

employed for research into cell sizing, DNA and chromosome analysis and many aspects of cell kinetics and microbiology. The exceptional versatility of the system allows it to keep pace with the researcher's interests, never to limit them.

Total Professional Support

Ortho's interest in cellular biology extends beyond producing instrumentation. For example, Ortho has developed Ortho-mune* monoclonal antibodies, the first panel (for research use only) of murine monoclonal antibodies reactive with human T lymphocytes. The company maintains wellequipped applications and training laboratories to develop new techniques and to provide consultative services for customers.

The results of these investigations and others are published in Protocols so that other researchers may share the results. Free copies are available by contacting Ortho.

Ask about the Cytofluorograf Flow Cytometer, 2150 and the complete range of Ortho services. Contact Ortho Diagnostic Systems Inc., Research Instruments Division, 410 University Avenue, Westwood, MA 02090 (617) 329-6100.

GUIDE TO AUT

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

PUT THE P-1 PUMP IN YOUR LAB...

. . . on the bench or hang it from a ring stand or scaffolding.

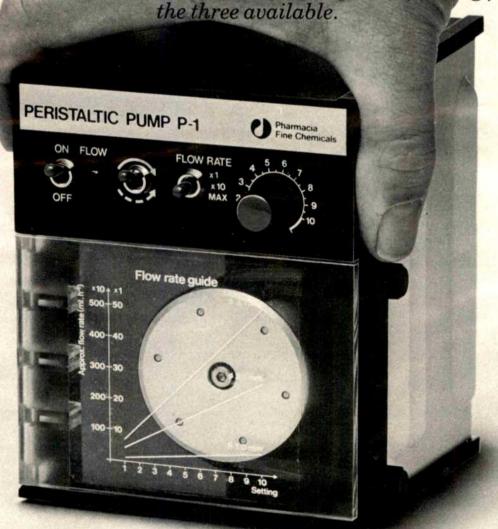

No matter where you put it, this peristaltic pump fits neatly into your chromatography system.

Connect it to your column.

Interface it with your fraction collector.

Hook it up to a controller.

No matter how you use it, the P-1 Pump delivers reliable flow of liquids from 0.6 to 500 ml/hr. Use it with almost any common buffer or solvent by selecting the proper grade of tubing from

For full details and specifications on the P-1 Pump, contact your Pharmacia Fine Chemicals representative today.

The third flight of the space shuttle *Columbia*, due on 22 March, is the first to carry scientific payloads

Science on the Space Shuttle		19:
The map sense of pigeons (a review)	J L Gould	204

Pancake detonation of stars by black holes in galactic nuclei	B Carter & J P Luminet	211
The rare earth elements in seawater	H Elderfield & M J Greaves	214
Genome instability in a region of human DNA enriched in <i>Alu</i> repeat sequences	B Calabretta, D L Robbersor H A Barrera-Saldaña, T P Lambrou & G F Saunders	

TERS TO NATI

A new model for white dwarf supernovae	R Canal, J Isern & J Labay	225
A Compton-cooled feedback mechanism for Cygnus X-1	P W Guilbert & A C Fabian	226
Alkylation of lead (II) salts to tetraalkyllead in aqueous solution	L J Snyder & J M Bentz	228
Aerosols of high chlorine concentration transported into central and eastern United States	R W Shaw Jr, F S Binkowsk & W J Courtney	i 229
Thermoluminescence reveals weathering stages in basaltic rocks	Y G Ögelman & S Kapur	231
A premonitory pattern of earthquakes in northern Greece	B C Papazachos, T M Tsapa & D G Panagiotopoulos	nos 232
Direct evidence of a subducted plate under southern Mexico	C Lomnitz	235
Delineation of the North Central Italian upper mantle anomaly	G F Panza, St Mueller, G Calcagnile & L Knopoff	238
Pb isotopic composition of ophiolitic volcanogenic sulphide deposits, Troodos Complex, Cyprus	ETC Spooner & NH Gale	239
Temporal changes in the inorganic carbon system of the south-eastern Bering Sea during spring 1980	L A Codispoti, G E Friederic R L Iverson & D W Hood	h,
Variability in the abundance of animal and plant species	R M Anderson, D M Gordon M J Crawley & M P Hassell	, 245
A possible case of hypervitaminosis A in <i>Homo erectus</i>	A Walker, M R Zimmerman & R E F Leakey	248
β-Endorphin is processed differently in specific regions of rat pituitary and brain	S Zakarian & D G Smyth	250
Insulin-like growth factor I stimulates growth in hypophysectomized rats	E Schoenle, J Zapf, R E Humbel & E R Froesch	252
H-noradrenaline release potentiated in a clonal nerve cell line by low-intensity pulsed magnetic fields	R Dixey & G Rein	253

Nature* (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Journals Ltd and includes the Directory of Biologicals (mailed in December) and Annual Index (mailed in February). Annual subscription for USA and Canada US\$198.50 (for subscription prices elsewhere, see next page). Orders (with remittance) and change of address labels to: Macmillan Journals Ltd, Brunel Rd, Basingstoke RG21 2XS, UK. Second class postage paid at New York, NY10010 and additional mailing offices. US Postmaster send form 3579 to: Nature, 15 East 26 Street, New York, NY 10010. © 1982 Macmillan Journals Ltd.

The Solution

for in vitro lymphocyte isolation

Ficoll-Paque®

FicoII-Paque is a sterile solution of density 1,077 ± 0.001gm/cm³ When used in the rapid procedure described in the package insert it consistently gives high yields of viable lymphocytes with purity greater than 90 percent.

Now available in two convenient sizes: 100ml bottles packed six (6) per case New-500ml bottles packed six (6) per case-for users who process large numbers of samples dailywhere economy is a necessity.

Both size bottles are designed for easy withdrawal of Ficoll-Paque, either by syringe through a septum or by pipette.

Try Ficoll-Paque now! It's the economical solution for your lymphocyte isolation requirements.

Pharmacia Fine Chemicals AB Box 175 S-751 04 Uppsala 1 Sweden

How Britain runs its Science How the US runs its Science

These two new *Nature* wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from *Nature's* offices in Basingstoke and New York.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

A special announcement to Nature subscribers:

Coming your way - FREE with your subscription to

RECTORY OF OLOGICALS

As a subscriber to Nature you will shortly be receiving our new annual Directory of Biologicals. A unique buyer's guide to biological laboratory products, it offers life scientists a comprehensive directory of what is on the market and where research workers can order these materials for their work.

Designed to meet the day-to-day needs of active biologists searching for the right product to use in the laboratory, its simple alphabetical listings cover all of modern life science research. Clear and easy to use, it lists more than 2,000 products commercially available, with the names and addresses of companies throughout the world that offer them for sale. Telex and telephone numbers give users direct access to sales offices in your area. Company entries also briefly describe each supplier's specialization. A separate section lists products by trade name or registered trademark, keyed to the companies in the guide.

Helpful essays on how to use the directory, safety procedures, how to purchase biological materials, and the future of modern biology, make this the most useful directory ever published for biological research workers.

As a subscriber, you will receive a handsome paperbound version of the directory. Watch for it ... it should be arriving any day. But if you think you need a copy to stand up against constant use in your laboratory or your library, or if you are not a subscriber, you can purchase the deluxe hardcover edition. (No paperback editions will be available after subscribers receive their free copy.) To order a hardcover edition, all you need do is fill out the form and mail it today

Circle No.26 on Reader Enquiry Card.

If your subscription was in effect on November 30, 1981, you will automatically receive a paperbound copy of the 1982 Directory of Biologicals. Those who entered subscriptions after that date will recieve the 1983 Directory of

Breakthrough in biotechnology

Just when research needed it, NENZYMES™ provided it. Now more and more people doing DNA-RNA studies are using these enzymes — because they are ultra pure. NENZYMES eliminate one variable from the many in molecular biology.

NENZYMES are tested for biological purity in two stages: First, in numerous specific assays of each produced lot (which are recorded for customer inspection); and again when used as integral components in our pre-packaged systems for DNA/RNA research. They have to be trouble-free before they go to you.

RNA Ligase is the latest addition to our line of DNA/RNA modifying enzymes. We also offer restriction enzymes as well as selected nucleic acids — all of the highest quality. Call us toll free for complete information on any of these products.

Mey surface for cell culture

Now you can choose the most suitable microcarrier for your culture

Cytodex microcarriers bring new opportunities to

- · routine and experimental cell culture
- production of viruses, interferon and other cell products
- in vitro studies on differentiation and metabolism

Cytodex 1

The microcarrier proven to be effective for growing more than 100 different cell types.

NEW Cytodex 2

Especially developed for better yields of viruses and cell products. Retains all the advantages of Cytodex 1 with the added benefit of new charged groups necessary for cell attachment localized only on the surface of the microcarriers.

Cytodex 3 The latest concept in microcarriers. The stable collagen surface gives improved attachment and yields of many cell types, especially those normally difficult to grow in culture. Enzyme digestion of the surface gives improved recovery and viability of harvested cells.

Make the most of your cell cultures. For more information on how Cytodex microcarriers give you new opportunities in cell culture contact us today.

Pharmacia Fine Chemicals

How Britain runs its Science How the US runs its Science

These two new Nature wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from Nature's offices in Basingstoke and New York.

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Natuse should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

Introduction **NUCLEAR** REACTIONS

G. R. SATCHLER

- Research staff member, Oak Ridge National Laboratory, Tennessee.

> 1980; £23; 336pp; ISBN 0 333 25907 6

Contents include - Some Background; Introduction to Nuclear Reactions; Elementary Scattering Theory; Models of Nuclear Reactions.

This book presents a summary of our present understanding of the Scattering and Reactions that occur in collisions between nuclei and is an introduction to the theoretical formalisms used to describe them. It is aimed primarily at readers in the undergraduate and beginning graduate student level but many others will also find it useful. The specialist from another field will find that this book is excellent background reading and the established nuclear physicist will find reading it to be helpful in refreshing the memory about areas in which he or she is not currently working.

For details contact Frances Roach, Scientific and Medical Division, Macmillan Press Limited, Houndmills, Basingstoke. Hampshire RG21 2XS.

New Translation System for Protein Processing

NEN introduces the first cell-free Translation System designed for the study of processed proteins.

Everything is in the package, including dog pancreatic microsomal membranes, dilution buffer, a positive mRNA control for monitoring system performance, and a protocol. Now you can spend less time preparing materials and free more time for evaluating results.

The Protein Processing Translation System,[35S]-joins our family of pretested systems

for molecular biology in offering both convenience and reproducibility. The components, listed below, are subjected to a complete processing assay prior to shipment. The resulting Methionine,[35S]- incorporation curve and autoradiogram are included in the quality control results you receive with the system.

Microsomal membranes
Microsomal membrane dilution buffer
Reticulocyte lysate
Translation cocktail
Methionine,L-[35S]Control mRNA
Salts and distilled water

To receive the information you'll need to evaluate this exclusive new system, simply circle the inquiry number below.

Circle No.10 on Reader Enquiry Card.

Custom synthesis of defined sequence oligodeoxynucleotides Superior quality Rely on P-L Biochemicals' expert team of organic, analytical and biological chemists to synthesize the oligomer you require—with assured precision. All intermediates used in our custom synthesis program are prepared from HPLC purified primary reagents. Once prepared, oligomers are purified and checked to assure proper base ratios and the removal of blocking groups. Maxam-Gilbert sequencing is employed to confirm your sequence. Versatility If you want to construct a primer from an amino acid segence, P-L can synthesize a mixture of oligomers containing more than one nucleotide at a given position. Or, if you're studying DNA structure, we can provide oligomers which contain a variety of modified bases. Low Price Whether you require 1 OD unit as a primer or 2,000 OD units for physical studies, P-L's custom synthesis can save you time and money—even compared to using a gene machine, Call Dr. Bill Gette today in Milwaukee, collect, at (414) 347-7384 for a quote on your defined sequence oligodeoxynucleotide requirement. **Fast Delivery** Once we've received written confirmation of your synthesis request, the oligomer(s) will be prepared and delivered to you within a matter of weeks. **Confidentiality** You can be assured that all custom synthesis inquiries and orders will be handled with complete confidentiality. Make P-L part of your gene team. (414) 347-7384 excellence In biochemistry Postfach 51 5401 St. Goar, West Germany Circle No.12 on Reader Enquiry Card.

Voyager 1 at Saturn

The new results from Voyager 1, which appeared in Nature of 20 August 1981 are now available in a glossy, 88-page booklet.

Copies can be ordered from the Nature offices in London, Basingstoke and New York at the following prices (including postage):

UK £2.00 each; USA & Canada US \$4.00; Rest of World £2.50 (surface), £3.50 (air)

Payment should accompany orders and may be in any currency at the prevailing exchange rate. Cheques should be made payable to Nature.

HUMAN SUBJECTS RESEARCH A Handbook for Institutional Review Boards

edited by **Robert A. Greenwald** and **Mary Kay Ryan**, Long Island Jewish-Hillside Medical Center, and **James E. Mulvihill**, University of Connecticut Health Center, Farmington

"This book provides perspective and guidance to those who have need to interact with the IRB process in a thoughtful and effective manner.... I now hasten to urge the potential audience... to read this book."

-Louis Lasagna, University of Rochester

Designed to fill the need for an operational guide to Institutional Review Board (IRB) function, this volume is a practical reference for IRB members, IRB staff persons, and researchers about to submit a project proposal to an IRB

approx. 300 pp., illus., 1982

INSECTS, EXPERTS, AND THE INSECTICIDE CRISIS

The Quest for New

Pest Management Strategies

by **John H. Perkins**, The Evergreen State College, Olympia, Washington

A carefully researched history of the development of integrated pest management, this provocative work explores the historical development of the crisis in insect control technology and demonstrates the need for revamping public policy toward entomological research.

324 pp., illus., 1982 \$29.50

GEOTHERMAL ENERGY DEVELOPMENT

Problems and Prospects in the Imperial Valley of California

by Edgar W. Butler and James B. Pick, University of California at Riverside

Offers an insightful analysis of the social impact preliminary development of geothermal energy resources has had on the Imperial Valley of California. Focuses on population impacts and economic data. Includes an important study of the social aspects that might limit geothermal energy development.

approx. 375 pp., illus., 1982

GENOTOXIC EFFECTS OF AIRBORNE AGENTS

edited by Raymond R. Tice, Daniel L. Costa, and Karen M. Schaich, Brookhaven National Laboratory, Upton, New York

Explores the genotoxic effects of specific airborne agents and details current in vitro and in vivo methods for assessing their genotoxic potential. Volume 25 in the series Environmental Science Research.

672 pp., illus., 1982

\$75.00

Now back in a second edition!

HANDBOOK OF NEUROCHEMISTRY

Second Edition

Volume 1

Chemical and Cellular Architecture

edited by **Abel Lajtha**, Center for Neurochemistry, Ward's Island, New York City

The completely new 10-volume edition of *Handbook of Neurochemistry* will be comprehensive, current, and the definitive reference in the area.

516 pp., illus., 1982

\$65.00

MITOCHONDRIA

by Alexander Tzagoloff, Columbia University

Details recent discoveries involving the structure and function of mitochondria, particularly those dealing with the genetic makeup of their DNA. A volume in Cellular Organelles, a series edited by Philip Siekevitz.

358 pp., illus., 1982

hardcover: \$42.50 paperback text: \$19.95

NIKON

NIKON HIGH-PERFORMANCE CF OPTICS. POSSIBLY THE FINEST EVER AVAILABLE.

INSTRUMENTATION

Nikon Optiphot microscope with CF objectives.

SIGNIFICANCE

Nikon's revolutionary CF optics virtually eliminate chromatic aberration. Within this series, several high-performance objectives significantly extend observation powers.

SPECIFICS

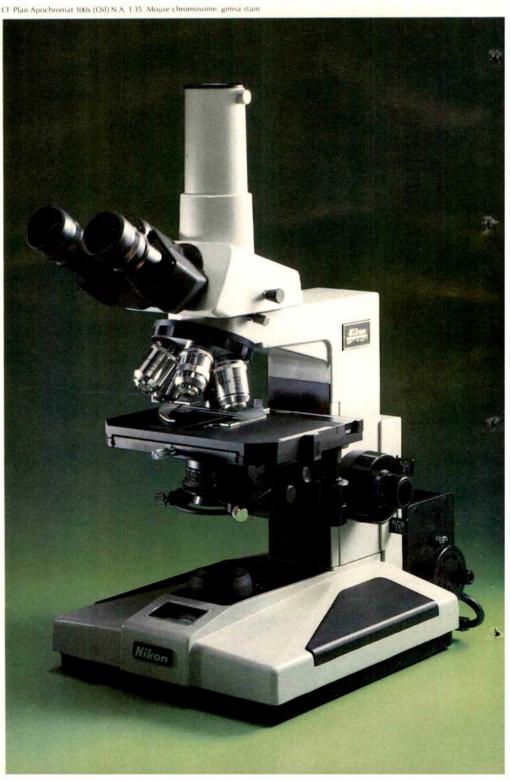

While all Nikon CF objectives provide a dramatic improvement in resolution, color rendition and contrast over the old compensation system, the following lenses are exceptional. The unique CF 2x plan apochromat has excellent image flatness for low power photography. The CF 40x plan apochromat, N.A. 0.95, dry, produces exceptionally bright, high-contrast images. Nikon's CF 100x NCG plan apochromat is designed to work without a cover glass. Its sharpness must be seen to be believed.

These remarkable optics are matched to a microscope body and illumination system equal to their performance the Nikon Optiphot. This totally new design is extremely stable. A standard 50-watt halogen Koehler illumination system covers all magnifications without need for adjustment, and the full range of Nikon accessories is available to match any assignment.

Extend your vision. Write: NIPPON KOGAKU K.K., Fuji Bldg., 2-3, Marunouchi 3-chome, Chiyoda-ku, Tokyo 100, Japan.

Nikon Extending Man's Vision

Circle No.32 on Reader Enquiry Card.

How Britain runs its Science How the US runs its Science

These two new *Nature* wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from *Nature's* offices in Basingstoke and New York.

US contributors please note

From now on, authors in the United States and Canada should send their manuscripts either direct to London or to the Washington office, whose new address is *Nature*, 991 National Press Building, Washington, DC 20045; manuscripts should no longer be sent to *Nature*'s New York office.

FMC, Marine Colloids Supports Polyacrylamide Gels

With Our New GelBond® PAG Polyacrylamide Gel Support Film

GelBond PAG is a 0.2 mm thin, transparent, polyester film designed for use as a support for polyacrylamide slab gel electrophoresis.

Convenient and ready to use, GelBond PAG sheets have a specially-treated surface which covalently bonds with acrylamide monomers during polymerization. The acrylamide gel rigidly adhered to GelBond PAG is easily handled throughout all electrophoresis, fixing, staining, and destaining procedures.

GelBond PAG is compatible with all popular staining techniques, including silver stains, and is recommended for use in IEF, 2D, SDS, nucleic acid sequencing, autoradiography, and fluorography procedures.

You can dry down the processed gels directly onto the GelBond PAG support for a permanent, undistorted record. Gels up to 7% T are simply and rapidly oven dried, while gels up to 15% T are dried using existing procedures, such as vacuum drying.

INTERESTED?

GelBond PAG is available in a versatile, attractively priced "Trial-Pack" containing five large sheets (304 x 400 mm), which can easily be trimmed to fit your particular apparatus. Included are complete instructions and a discount coupon good for 10% off your next purchase of any standard-size pack of GelBond PAG sheets. GelBond PAG is currently available in sheet sizes to fit all popular equipment. Please call us with your special requirements.

FOR FAST SERVICE

Call us toll-free at 1-800-341-1574 and order your GelBond PAG "Trial-Pack" today. Or write FMC Corporation, Marine Colloids Division, BioProducts, Rockland, Maine 04841

Visit us at FASEB, Booth #'s B-39 & 41.

GelBond is manufactured for FMC by the 3M Co.

MISCELLAN

100 years ago 706 Books received 787 Product review: Achema '82 xxiii Classified advertising XXV

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

WE CAN'T GO ON LIKE THIS

News about all our labeled research products simply won't fit in a single-page ad any longer.

But not to say goodbye. You can keep in touch with all of our new research products — and then some — in our New Product News, a very readable multi-page bulletin that mails out every month. If you're not receiving it already, be sure to circle this inquiry number.

Circle No.01 on Reader Enquiry Card.

How Britain runs its Science How the US runs its Science

These two new *Nature* wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from Nature's offices in Basingstoke and New York.

MISCELL/

100 years ago Announcements Classified advertising 810 vii viii

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

INTERNATIONAL ORTALITY STATISTIC

Michael Alderson, Professor of Epidemiology at the Institute of Cancer Research

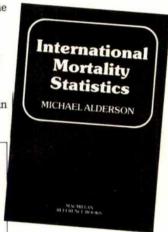

For the first time ever, 20th century mortality statistics are now available in a single volume, working with a common statistical base and a common set of premises.

405 pages of clearly laid-out tables present mortality statistics for 32 countries, 25 of them European. They are tabulated by sex, five-year periods from 1901 to 1975, 178 causes of death, and country.

Six introductory chapters give full explanations of the statistical method used, the validity of the data, and alignment of the international classification of diseases. This enables you to make your own evaluations and comparisons using the data, rather than providing a textual interpretation of the tables.

If you want to examine long-term mortality trends in one country, or to compare patterns in different countries, this book is your essential reference.

The European countries examined are: Austria, Belgium, Bulgaria, Czechoslovakia, Denmark, England and Wales, Finland, France, Greece, Hungary, Iceland, Ireland, Italy, Luxembourg, Netherlands, Northern Ireland, Norway, Poland, Portugal, Romania, Scotland, Spain, Sweden, Switzerland and Yugoslavia. Outside Europe data are presented for the USA, Canada, Japan, Australia, New Zealand, Chile and Turkey.

THE HAZARD FROM **ANGEROUS** XOTIC DISEASES

John C. N. Westwood, Professor and Chairman of Microbiology and Immunology, University of Ottawa.

This book analyses the epidemic hazards of lethal and highly infectious exotic diseases to the very susceptible communities of the developed world.

Professor John Westwood, one of the foremost authorities on infection control, assesses the nature and scale of the problem, and gives a detailed examination of six diseases which pose the greatest threat - Lassa, Marburg, Ebola and

Yellow Fevers, Plague and Smallpox.

He outlines an appropriate level of response to ensure adequate control and containment, both in the community and in hospitals.

. . a thoughtful and well-written book. As might be expected from a former director of virus research at the Microbiological Research Establishment at Porton Down, the description of the diseases and their causative agents is clear and accurate'

- British Medical Journal

. most warmly recommended . . . Westwood has made a valuable contribution' - The Lancet

Universities, profit and research

The presidents of five major research universities will meet privately later in the month to work out guidelines for commercializing research. They cannot be allowed the last word.

Dr Donald Kennedy, president of Stanford University, seems to have been granted his wish, frequently expressed a year ago, for a high-level conference on the problems of the relationships between universities and the commercial interests in recombinant DNA research. Later this month (and not far on the Californian coast from Asilomar), he and four other university presidents, (California, Caltech, Harvard and MIT) hope to assemble with select teams of their senior colleagues and industrial partners to hammer out guidelines for the proper conduct of joint commercial ventures. Although this occasion cannot match that in 1973 at which a relatively unstructured gathering of molecular biologists agreed, off their own bat, that there should be guidelines to regulate the conduct of recombinant DNA research. there is nothing reprehensible about what is now proposed. The five universities concerned are those which have been most intimately caught up with the commercialization of recombinant DNA research. What more reasonable than that they should arrange privately to meet to talk about their problems and to agree, if possible, to some common approach to the problems that have not yet arisen? There is no reason why they should be deflected from this sensible — and overdue — exchange of ideas by the wish of others, congressmen or other universities, to join the action.

Equally, however, it would be wrong for those planning to meet three weeks from now to think that what they agree among themselves about the proper relationship between universities and outside commercial interests will apply to other universities and other commercial interests. Indeed, the question is bound to arise whether any guidelines arrived at can be successfully applied even within the five participating universities — one of which, the University of California, is already in some difficulty with the state authorities on the customary exemption of academics who are also state employees from the standard constraints on conflicts of interest. This month's private meeting is bound to sharpen questions about the propriety of what the university intends. But there are also limits to the extent to which even the private universities can write their own tickets into a brave newcommercial future. Already, as the affairs of the University of California's Davis campus have shown (see p.6), the interests of graduate students and those who teach them are not identical and, for a research university, the contentment of the graduate students takes precedence over that of the faculty. More generally but more importantly, the universities, especially the best among them, are public institutions embedded in a society which is perfectly entitled to views on how they should be run. And there are tax-exemption rules to give force to public opinion. This month's private conference could do a useful job, especially if it follows the sensible course of making public its conclusions. But it cannot be the last word.

What, in the circumstances, should Dr Kennedy and his colleagues talk about? Their first task must be to preserve the integrity of the institution of the university. Since the first excitement about the commercial potential of biotechnology five years or so ago, most universities have been in two minds about the roles that they should play. The prospect that they might, as a consequence of the cleverness of individual members of their faculties, be partly immunized from external financial pressures, has naturally been attractive. And government (not merely in the

United States) has been urging that universities should find other than public sources of financial support. But, dare it be said, not all biotechnology and not all biotechnologists automatically satisfy the criteria of excellence which universities, and especially the good universities, seek to apply to their affairs. How, then, to channel an institution's enthusiasm into support for some activity that will make a little money while giving proper academic attention to other activities that bring no profit? The ideal is that university faculties should be even more zealously encouraged than at present to decide among themselves between the good and the less good. The ideal is simple, but its practice will be hard.

Problems concerning people are likely to be even more important. It is essential that means should be found of making sure that universities cannot be fairly charged with misusing their students, perhaps by allowing faculty members to turn some piece of graduate research to commercial use. Similarly, because the effectiveness of universities requires a certain seemliness within the whole body of faculty and students, it is important that no single member of such a community should be thought capable of turning his academic position into unreasonable riches. And however intellectually absorbing may be the task of turning a bright idea into some commercial innovation, there must be a limit to the extent to which a university can let full-time members of its faculty function as entrepreneurs while remaining in the fold. Stanford has already made some headway with its internally promulgated rules for deciding how financial benefits from commercial enterprises should be shared between individuals. departments and the university. What is needed, now, is not so much a wider adoption of some standard formula as a better understanding of how such arrangements are working. Although biotechnology still seems the most conspicuous opportunity for turning academic work to profit, there are other betterestablished fields (engineering, for example) from which much can be learned. The trouble is that a clear understanding of this point will require an investigation, not just a two-day meeting.

British nuclear weapons

New nuclear submarines may be the best buy; talking to the French would be safer.

The British government's present dilemma about nuclear weapons policy is at least familiar. For at least the past twenty years, there has been continuing doubt about the most suitable means of preparing to deliver the modest British stock of nuclear explosives. It all seems so much more complicated than in the faroff 1950s when Britain, having become a nuclear power in a fit of absence of mind, was able to keep up with the superpowers with the help of home-built aircraft. Since then, it seems, there has been nothing but trouble. Knowing that a nuclear striking force is no more credible than the means by which explosives can be delivered to intended targets, the British government embarked on the development of intermediate-range missiles (remember Bluestreak?) and contour-following aircraft (the TSR2). But the pace turned out to be too demanding. This is why, in 1962, the British government leapt at the deal offered by President John F. Kennedy and took out an option first on the weapon called Skybolt (an early air-launched cruise missile that was promptly

0028-0836/82/090001-02\$01,00 © 1982 Macmillan Journals Ltd

cancelled) and then on *Polaris* missiles carried in British-built submarines. Now, with both the submarines and the rockets which they carry nearing the end of their useful life, the British government is doing what must now seem natural, and is planning to follow the United States in replacing *Polaris* by its more powerful (and accurate) successor, *Trident*.

The whole sorry tale should be an object lesson, and a warning, to other states flirting with the notion that they, too, might become second or third-rank nuclear powers. It should also help to moderate some of the more alarmist notions of how easily nuclear weapons might proliferate. For nobody believes that the cost of this still incomplete system will be contained within the £6,000 million (spread over fifteen years) that the Ministry of Defence is talking about. The argument that the total cost will be. in any case, only three per cent of the British defence budget over the fifteen-year construction period is hardly what matters — the cost works out at seven per cent of the likely equipment budget over that period. This prospect chimes ironically with the British government's decision to put several relatively new items of defence equipment on the secondhand market — the aircraft carrier Invincible is for example being sold at cost to Australia, while the Indian government is hoping to pick up an Antarctic research vessel (see Nature 25 February, p.640). Yet the cost of the British weapons programme, blessed by the Bermuda agreement, is undoubtedly far less than would be entailed by complete independence — as French taxpayers should be well aware.

The cost of being a serious nuclear power, even a small one, is onerous. The British government's domestic critics (who, on this issue, include a great many of its natural supporters and even one field-marshal) have made several telling points. Conventional defences will be weakened just when they need to be reinforced. The cost of Trident could better be spent on more creative projects. And now, for the first time since 1958, there is a risk that bi-partisan agreement that Britain should have some kind of nuclear defence force will disappear. No doubt each of these complaints carries some weight. The surprise, however, is that the argument between the British government and its critics has been confined to more or less tactical questions. Would cruise missiles be a better buy than Trident? (The answer is maybe.) Would the same expenditure on conventional forces contribute more to the defence of Western Europe? (Almost certainly yes.) The curious aspect of the row about Trident, however, is that so little is being done to clarify the reasons for and against the retention of an independent nuclear force of any kind.

In the 1950s, it was different. The decision then to develop an independent nuclear force stimulated a vigorous and informative argument. Serious opinion was split three ways. At one extreme were the unilateral disarmers, whose residual legatees seem now more anxious to prevent the siting of United States nuclear weapons in Britain than to re-examine British nuclear policy as a whole. Then, in the 1950s, what might be called liberal military opinion argued that British nuclear weapons might have a useful role in an escalating European conflict. The government view, which prevailed and has since stuck, was that an independent British nuclear force would help to cement the commitment of the United States to its European alliances, for it would be easier to stand aside from a conventional than from a nuclear conflict. Diplomatically, of course, the argument was never put so directly, for that would have invited the United States Congress to refuse to sanction the technical assistance with which the British nuclear force was built. Now, for what it is worth, the British case appears subtly to have changed. Last weekend, the Secretary of State for Defence, Mr John Nott, was arguing in a television interview that the Trident force, like and with its French equivalent, would come into its own if the pattern of alliances in Western Europe changed, leaving both France and Britain to look after their own defence.

This argument is essentially the same as the Gallois doctrine in the 1950s to justify the French nuclear force. To defend itself with nuclear weapons, a state merely has to equip itself with the means of inflicting damage on a potential enemy proportional to its own value as a prize. The argument is persuasive, but it conceals a serious danger — its universal applicability. If French and British

nuclear forces are justified in this way, why not Swiss or Swedish? The practical answer may be that at this late stage in the development of nuclear technology, the entry fee would be too high. But nobody can be sure. And if the British government is indeed edging round to planning for a world in which the pattern of European alliances may have radically changed, should it not now be talking to the French government, which must share the long-term interest that Europe should not become a collection of supposedly independent nuclear powers. And, by the same test, there is much to be said for going as slowly as possible with *Trident*, for the sake of all the money that may then be saved.

Chemical inspections

British proposals for verifying a chemical weapons treaty should be taken seriously.

The abiding trouble with arms control is that there is so much talk about it. Even if the apparently endless negotiations in Vienna on Mutually Balanced Force Reductions are forgotten (which is probably the most appropriate course), there are at present no fewer than four settings for serious discussions on the subject: the European Security Conference in Madrid (made necessary by the Helsinki agreements), the superpower talks in Geneva on European nuclear weapons, the standing Committee on Disarmament now also meeting in Geneva and the labyrinthine preparations for the United Nations session on disarmament, planned for June. Of these, however, only the two Geneva meetings are for the time being serious, and the United States and the Soviet Union have so far kept to their agreement not to broadcast news of what is going on. This is why it is refreshing that something sensible is happening at the other meeting in Geneva, that of the Committee on Disarmament.

The British government, often pilloried (as in the preceding account of its nuclear weapons policy), last week startled the Committee on Disarmament by tackling head-on one of the most difficult of the technical problems impeding the negotiation of a treaty to get rid of chemical weapons — that of verification. The problem is by now all too familiar. The agents potentially usable as chemical weapons can be made in manufacturing plants which are indistinguishable from those outside from the used for making pacific chemicals of various kinds. Although chemical munitions plants are by convention usually sited far away from civilian populations, there is no reason why their isolation should be ostentatious. The result is that remote surveillance, from satellites for example, cannot reliably indicate whether a state that has signed a treaty to dismantle its stocks of chemical weapons and to refrain from making more is actually keeping to the rules.

The British view, put forward last week, is that a sufficient degree of assurance against violations of a treaty could be provided by a judicious use of an expert committee, the monitoring of the flow of chemical raw materials through chemical processes, a complaints procedure and the judicious use of on-site inspection. Nobody can at this stage guess how the proposal will be received. The Soviet Union is notoriously sensitive about proposals for on-site inspection, but is not the only manufacturer of chemicals that is also touchy about its sovereignty. Sooner or later, however, on-site inspection is going to have to be a component of arms control agreements — and was, two years ago, accepted by all the nuclear powers to be a necessary part of the test-ban treaty then in draft. So the British government deserves encouragement for having raised the issue again. And it deserves some credit for trying to breathe life into an arms control project that has been too long forgotten since the superpower talks on the subject broke down in 1980. For this is eminently a field in which all potential parties to future conflicts would gain from an agreement not to manufacture weapons whose military value is as much in doubt as that of chemical weapons, whose production, maintenance and occasional disposal is a constant threat to the domestic population and whose agreed abolition would rid the world of a great nuisance and a needless cost.

Clouds on biotechnology horizon

Companies run short of sales and capital

Washington

The US biotechnology industry is coming down to earth with a bump, as various companies begin to experience difficulty in raising the capital needed to finance ambitious expansion plans.

Last week, for example, Bethesda Research Laboratories (BRL), one of the more successful of the many small biotechnology companies to have been set up within the past few years, announced that it was cutting back its workforce from 450 to just under 300 because of cash-flow problems, and was re-thinking plans for moving into larger facilities.

Only six months ago, the company was talking of a public offer of its stock, seeking to raise \$40 million to finance expansion over the next two or three years.

Other companies are experiencing the same problem, although none quite so dramatically. San Francisco-based Genentech, for example, is expected to have to think hard about how it is going to raise the new capital it will soon need for future expansion, although it said last week that at present the company was growing at its projected rate.

So far, out of more than 150 companies set up in the past few years, only one — Applied Genetics of Boston — is known to have folded. In most cases, according to Wall Street analysts, the cutbacks in growth being reported reflect a shake-out that had long been expected, partly a reaction against a period of over-expectation.

They point out that in the case of BRL, for example, the company is retaining most of its scientific personnel, particularly in the area of restriction enzymes for which it has established a worldwide reputation. The cuts are being made in more peripheral areas in order to maintain a healthy core.

The problems being experienced by the biotechnology companies are caused less by the current recession than by the fact that it is now much more difficult to raise new equity than it was even six months ago.

After the dramatic sale of stock in Genentech exactly a year ago, when shares rose from \$35 to \$80 on the first day of trading, shares have now stabilized around the original figure. Shares in Cetus, which went public with a far bigger proportion of its equity six months later, have slipped from \$25 to around \$13. The latest public newcomer, Collaborative Research of Waltham, Massachusetts, also received a relatively cool reaction when it went public last month.

Investment analysts claim these figures reflect a new realism in the market, which recognizes that although genetic engineering techniques still offer a large commercial potential, there is still some way to go before anyone starts reporting a substantial profit. Two weeks ago, for example, Genentech reported that profits for 1981 were double those of 1980, but at \$300,000 these compare unfavourably with a revenue of \$21.3 million.

In the case of BRL, since the company is still private and therefore does not have access to large amounts of capital, it has had to rely more heavily on the sale of laboratory products, which last year generated an income of over \$10 million. This has made the company particularly sensitive to any fluctuations in the market, contributing directly to the decision to "restructure" its activities.

BRL is divided into four divisions covering research products, instrumentation, genetics research and molecular diagnostics. Staffing cuts are being distributed across all four divisions, and although ten PhDs were among those who had received their notice, the company says that in general the cuts had fallen less heavily on scientists (who make up about one-sixth of employees) than on other staff.

The cuts mark the end of a period of

"NEVER MIND-IF THINGS LOOK UP, WE'LL CLONE A FEW MORE."

spectacular growth for BRL. Formed by Stephen Turner, who previously worked with Becton-Dickinson, with two other employees in 1976 and based close to the National Institutes of Health which have been among its most important clients for restriction enzymes, the company had sales of \$350,000 in 1977, \$1 million in 1978 and \$5 million in 1980.

Asked in an newspaper interview last September how he viewed the future prospects for his company, Mr Turner admitted that the market for his products was rapidly filling up as the expansion of new genetic engineering laboratories levelled off. "I was taught long ago that the goal of business planning is survival, not dominance", he said.

David Dickson

Cohen-Boyer patent extended

Washington

The US Patent Office last week informed Stanford University and the University of California, San Francisco (UCSF) that it has accepted their claims for a patent on any microorganism which is made using the genetic engineering techniques developed by Dr Stanley Cohen of Stanford and Dr Herbert Boyer of UCSF.

The techniques themselves were granted a patent just over a year ago. The patent was offered for licensing last summer, and last week Mr Andrew Barnes of Stanford's Office of Technology Licensing said 73 companies have so far agreed to pay the \$10,000 annual licence fee (five times which is credited against any future royalty payments).

Initially, applications for patents on both the techniques and the products of the techniques were filed simultaneously. However, in the light of the Patent Office's subsequent challenge to the legality of patenting living organisms — eventually resolved by the US Supreme Court, which agreed that they could be patented — the application was split into two parts.

Of the two, Mr Barnes said that the process patent already granted was considered by the universities to be the more significant. He added, however, that

the product patent, which it had been generally anticipated that the universities would receive, could strengthen their hand in any future legal proceedings.

For example, if the process patent alone had been allowed, foreign companies might have been tempted to import into the United States products made in countries where the techniques had not been patented, and the universities would have had to challenge this under a slightly ambiguous ruling from the International Trade Commission. Now that the product patent, expected to be formally granted in a few weeks, has been allowed, it will be a legal challenge to such imports.

The new patent will cover any recombinant plasmid made using the techniques developed by Dr Cohen and Dr Boyer, provided that the vector is compatible with the cellular host organism. The universities have also been allowed a patent on the transformant itself, providing this is a unicellular organism, such as a bacterium or a protozoan; human and plant cells, however, would not be covered.

Rights to the use of the products are already included in the licensing agreement which Stanford and UCSF have been negotiating with interested companies.

Pharmaceutical research

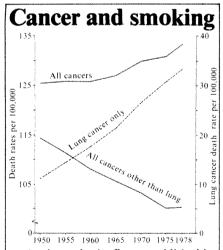

New tenants

The Swiss pharmaceutical company Sandoz has decided to set up a new research institute in the neurosciences at University College, part of the University of London. According to Mr E.J. Fullagar, director of Sandoz's UK operations, the new institute reflects the company's belief in the quality of British researchers — it hopes to recruit almost all its staff in Britain — and in the continuance of top quality British research. But the institute may help to persuade the British regulatory authorities to view more favourably applications for price increases on Sandoz's products.

The new institute, the first that Sandoz has set up on a university campus, is an experiment. According to Mr Fullagar, the venture will be no less expensive than building an institute on Sandoz's own premises. The hope is that spin-off from close links with the college will more than pay for any extra costs incurred.

The company chose to site its institute at University College partly because the two have collaborated successfully in the past on clinical studies and partly because the college's research in the neurosciences matches its own interests. The new institute will be chiefly concerned with the role of neurotransmitters and neuromodulators in the nervous system.

Although the institute will be entirely independent of the college, employing

As shown in the figure, published in "The Health Consequences of Smoking: Cancer 1982" (US Department of Health and Human Services), during the period 1950 to 1978, the overall cancer death rate increased. This trend results from a remarkable increase in lung cancer death rates. However, if lung cancer deaths are excluded, the overall cancer mortality rate has fallen. This is largely a result of improved diagnosis, treatment and survival times for cancer sites not associated with cigarette smoking, such as prostatic, colorectal and breast cancers, while lung cancer survival remains dismal.

about 60 of its own research staff, the plan is that there should be a close relationship between the research staffs and that the college might look to some institute staff for teaching.

The college, which although relatively well endowed is nevertheless suffering from university cutbacks, will benefit financially. Although Sandoz's rent is only nominal, the company will pay the college a £2.5 million premium and thereafter pay for overheads and services such as library and catering facilities. The money will help the college out of some of its difficulties, in particular those of completing capital projects abandoned because of cuts in its grants from the University Grants Committee. Thus work begun on a new chemistry building in the early 1970s will now be completed. Sandoz will refurbish the building vacated when the chemistry department moves into the new building to be used by the new institute.

Sandoz estimates that it will spend £5 million on setting up the institute, divided equally between payments to the college, the costs of refurbishing and the cost of equipping laboratories. The laboratories will not be ready before September 1983 at the earliest. Hence, according to Mr Fullagar, it is still too early to describe the research programme in detail, or to say whether the college and institute will cooperate on joint programmes and, if so, how. Patents taken out on the results of research supported entirely by the institute will, however, belong to Sandoz. But where research has been jointly supported, the college's lawyers will advise.

Sandoz, therefore, seems cheerful about the long-term prospects of British university research. Its view, however, is not shared by Biogen, the Swiss-based pharmaceutical company, which has chosen not to site its third laboratory in Britain on the grounds that the university cuts may irreparably damage British biotechnological research.

Biogen plans to set up a new laboratory along the lines of those at Cambridge, Massachusetts, and Geneva. The idea is that the laboratory should be separate from but near to a university department with considerable expertise in recombinant DNA research. The company says that it cannot justify setting up a laboratory near a suitable British university because no department is guaranteed to escape the ill effects of the university cuts. So it is looking elsewhere, in particular in Belgium and West Germany.

The new laboratory is intended to complement the work of Biogen's existing laboratories and to allow the company to spread its research between institutions employing no more than 75 research staff. According to Walter Gilbert, Biogen's chief executive, Biogen will nevertheless consider employing British biotechnologists of suitable calibre who apply for posts in any of its laboratories.

Pesticide data

Row on access

Washington

The latest move in the lengthy battle over access to scientific data on the medical effects of pesticides came last month with the US Environmental Protection Agency (EPA) asking Congress for authority to write its own rules for the release of such information. Members of the House of Representatives' Agriculture Committee have tried to find a compromise between public interest groups demanding open access to the data submitted to the agency and pesticide manufacturers, who argue that the unrestricted release of such information would benefit their commercial competitors.

The manufacturers have been pushing for changes in the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA), first passed by Congress in 1972, which provides any individual with access under the Freedom of Information Act to scientific and medical data submitted to EPA as part of the regulatory process of registering a new chemical. Attempts at revision are being fought by a coalition of health groups, conservationists and labour unions which argues that the demands being made by industry would make it impossible, for example, for research scientists to communicate openly the results of their analysis of the data.

In its zeal to respond to public protests about the potential health hazards of new pesticides, Congress passed in 1978 stiff new amendments to FIFRA. These included a specific clause saying that data on the medical effects of a pesticide were not to be treated as a trade secret, and were not therefore exempt from freedom-of-information requests.

Since then, manufacturers working primarily through their Washington-based lobbying organization, the National Agriculture Chemicals Association (NACA), have tried to challenge the clause several times in court. The companies claim that the data produced in their research laboratories are private, and that the government's requirement that they be handed out on demand is a violation of constitutional rights.

So far, the courts have upheld the validity of the new law. The manufacturers have responded by turning their attention first to Congress, in the hope of having the law revised, and more recently to EPA with the prospect of receiving a more sympathetic hearing.

Last summer Mr George Brown, previously a prominent member of the House Science and Technology Committee and now chairman of the research subcommittee of the House Agriculture Committee, introduced a new bill that would limit the conditions under which the data could be released. These revisions would make the data available only to approved

individuals, who would have to take notes from reports made available in EPA reading rooms. Labour union representatives and people working in the health services would be able to borrow complete reports, but would not be allowed to divulge the contents to others. No employee of another chemical manufacturing company would be allowed access to the data; and nobody would be allowed to make a complete transcript of the research reports.

Members of the subcommittee staff argue that such provisions, provide a compromise between industry's desire to protect confidential research data, and the public's right to information on the risks and benefits of chemicals used for crop protection. Both parties in the dispute disagree.

The manufacturers were initially enthusiastic about the changes proposed by Mr Brown, but their support has evaporated as the amendments have been revised to take into account some of the objections of those claiming to be defending the public interest.

Environmentalists and labour union groups are seizing this "window of opportunity" between the failure of the last industry challenge and the eventual tightening up of administrative requirements to get as much information on existing pesticides out of EPA as they can. EPA administrator Anne Gorsuch informed a coalition of such groups that the agency intended to respond to demands for pre-registration data on eleven chemicals as well as data on alternatives to 2.4.5-T

At the same time, EPA has been talking with industry representatives, who have asked for an "administrative stay" on the release of data under the Freedom of Information Act, and are said to be helping EPA to develop a set of restrictions that would be both legally defensible and commercially acceptable.

Moves in Mongolia

The new president of the Mongolian Academy of Sciences is Dr Choydogiyn Tseren, a 42-year-old physicist. Dr Tseren, who is a graduate of Moscow University, has spent a considerable time (1966 to 1971 and 1974 to 1980) at the International Nuclear Research Institute at Dubna. In 1980, he returned to Mongolia to become academic secretary of the academy.

Dr Tseren's appointment as president of the academy, which was effected by a special decree of the presidium of the People's Great Khural (parliament) of Mongolia, followed the dismissal, at the beginning of the year, of the previous president, Dr B. Shirendev, for his "misunderstanding" of the nature of socialism, a term which apparently covered hard currency irregularities.

Coal gasification

Belgian first

Brussels

A gleam of hope for Europe's coal production came with the announcement this month that the first gasification of coal at depths of nearly 1,000 metres would take place this May in Belgium. The technique has been used for some time in the Soviet Union and in other countries but never at these depths. If the project at Thulin near the French border lives up to its promise it will turn many of the inaccessible or abandoned coal deposits in Europe into a new source of energy.

The Thulin project is run by the Institute for the Development of Subterranean Gasification, 60 per cent of whose funds are provided by the Belgian and German governments, the other 40 per cent by the EEC.

The retrocombustion technique used works by burning the coal in situ and then pushing the gas through the coal strata to a second outlet. The creation of such a circuit at this depth means working with high pressures and ensuring that the coal is permeable enough to allow the passage of the gas to the second bore hole. Air is forced down the first bore hole and ignited at a temperature of some 400°C, so that the coal ignites spontaneously.

The problem is that the deeper the coal lies the further away the second bore hole must be. At 1,000 metres, the gas would have to travel between 80 and 100 metres. The costs rise with the depth of coal deposits, as it becomes increasingly difficult to complete the circuit. Oil can be extracted at depths as low as 4,000 metres, but with coal the deeper one goes the more impermeable it is. At Thulin the problem has been overcome by forcing compressed air along the vein in order to enlarge the existing natural fissures.

The commercial applications of the technique are still uncertain, as it depends not only on energy prices but also on the coal seam thickness. Nevertheless, the British Coal Board is following the experiments with interest as a potential means of exploiting North Sea coal.

So far the gasified coal being brought to the surface in Belgium is of low quality, yielding some 2,500-3,000 kcal per m³. However, specialized treatment could increase this to 12,500 kcal per m³. At first, therefore, the gasified coal would simply be burnt in power stations but there is speculation that it could one day compete with pressurized liquid gas — now used to run cars.

The earliest date by which the technique could bring commercial benefits is put at 1990. Nonetheless the Belgian energy minister, Etienne Knoops, seizing on a spark of optimism to brighten his country's current troubles, remarked, "We are today inaugurating the birth of a new natural source of riches for our country".

Jasper Becker

Dutch energy policy

Talking shop

Waalre, The Netherlands

The steering group set up in The Netherlands to referee the national debate on the country's energy problems now finds itself grappling with financial constraints — and with some political disenchantment.

The long-running and often acrimonious Dutch energy debate began in the early seventies with the government's "energy memorandum", but got under way in earnest only last June, with the appointment of a nine-strong steering group of politicians, energy experts, scientists and labour union representatives, given the brief of organizing the public discussion.

Some years ago, a budget of £3.5 million (Df1.17 million) was allotted to the steering group to cover total costs for the two-year discussion, and the group now has a staff of 14 academics (including a theologian) and 17 administrators. Most of the money was intended for subsidies to the various groups in society seeking to work out alternative energy policies to that put forward by the government.

In January this year the steering group awarded a first round of grants, totalling £1.5 million, to 31 groups including a consortium of 50 environment groups and employers' organizations. This was only half the amount asked for by the applicants, and reflects the financial pressures being felt by the steering group. In February the government decided on a budget of around £5.5 million for the steering group instead of the £7.4 million requested, of which £1.8 million is intended for subsidies, not the £3.1 million asked for.

Discussions on the budget revealed political discontent over the policies of the steering group, discontent which at one time threatened to bring an early end to the project. Some members of parliament and press commentators were critical of the way in which the first batch of subsidies was allocated — in particular, complaining that too much money (roughly half the total) went to pro-nuclear groups having close ties with industry, and in no desperate need of the cash.

The "information phase" of the discussion is now due to be completed by the end of 1982. The aim of this part of the process is, in the words of steering-group chairman Maurits De Brauw, a former minister for science policy, "to give the public the unique chance to present alternative, scientifically based policy ideas, equivalent to those of the establishment". When that is over, a further short public discussion will follow, probably concentrating on three or four energy/economy scenarios selected from the initial phase.

Whether or not this attempt at involving all segments of Dutch society in a major

decision will actually yield some clear results remains to be seen. But parliament has at least decided to await the final report from the steering group, expected at the end of 1983, before making its final decision.

Casper Schuuring

Commercialization of research

Student dilemma

Washington

Renewed public controversy has arisen about the connections of various faculty scientists at the University of California's Davis campus with a local research company Calgene, particularly over the effect these could have on graduate students.

Last October, plant biologist Dr Ray Valentine was told by the university that he must either relinquish his position as chief investigator on a \$2.3 million grant to the university's experimental station from the Allied Chemical Corporation to support his work on nitrogen fixing (nif) genes, or give up his contracts with Calgene, of which he is a co-founder and vice-president (Nature 8 October 1981, p.417).

The university's ultimatum followed the discovery that Allied Chemical had also agreed to buy a 20 per cent equity interest in Calgene. Dr Valentine subsequently agreed to step down from the university research project. However, the publicity helped spur the state's Fair Political Practices Commission into recommending that university researchers should no longer be allowed a blanket exemption from conflict-of-interest laws routinely applied to other state employees.

The latest dispute has arisen over charges that some graduate students in Dr Valentine's laboratory have been placed in a difficult position since it became clear that some of their research on the genetics of nitrogen fixation could have significant commercial consequences.

The campus daily student newspaper last week published extracts from memoranda written by faculty members expressing concern about the impact of Dr Valentine's involvement with Calgene on the academic functioning of the university.

One set of memoranda relate to a decision by four of the five graduate students to transfer their research, with Dr Valentine's approval, to another laboratory on the campus. Dr JaRue Manning, professor of bacteriology, said that graduate students have revealed several common concerns. The first was Dr Valentine's statement that it was the students' responsibility "to meet with Calgene personnel and establish that their graduate research project is not being conducted at Calgene".

The second factor quoted by Dr Manning was what he described as the switching of student research projects as a condition for continued support after students have spent up to two and a half years on a project. "Regarding the second factor, while there is certainly a need to coordinate research activities with objectives stated in grants, etc., the manner in which these changes were made raise a number of questions as to the actions taken."

Other memoranda raise more general issues about the effects of intensifying links between university researchers and companies such as Calgene. In a note to Dr Charles E. Hess, dean of the College of Agricultural and Environmental Sciences, Dr Emanuel Epstein, professor of plant nutrition at Davis, suggests that scientists are no longer keen to exchange research data with each other as soon as it comes off the scintillation counter or the electrophoresis cell.

In another memorandum to Allen G. Marr, dean of graduate studies and research, professor of zoology Robert L. Rudd complains that plans by Calgene to initiate a research project which competes with the dissertation research objectives of one of his graduate students was "an infringement on academic freedom and potentially harmful to graduate education in general".

Both Dr Epstein and Dr Rudd said last week that they were not opposed, in principle, to collaboration between university research scientists and the private sector. As a land-grant college, the Davis campus of the University of California has long had close links with both local farmers and agricultural companies. Both, however, were concerned that public reaction to the tensions caused by the recent rush to exploit research findings in genetic engineering could lead to bureaucratic controls that might themselves be an infringement on academic freedom.

The state's Fair Political Practices Commission met on Monday to discuss whether it should give final approval to the suggestion, approved by a 3 to 2 majority at its January meeting, to require university researchers to make public any financial interest they may have in a company which is sponsoring their research (*Nature* 4 February 1982, p.357).

The internal memoranda appear to have been leaked as part of a campaign by the California Rural Legal Assistance to persuade the commission to go further and require university scientists to disclose all their financial commitments in outside companies, whether or not the companies are providing research funds to them.

Dr Valentine did not return telephone calls last week asking him to comment on the questions that had been raised about the position of the graduate students. A spokesman for Calgene said that that the company did not employ any Davis students, and was not sponsoring any research at the university. (About thirty Davis faculty members are reported to be acting as consultants to the company.)

David Dickson

Polish crisis

Questions asked

One of the casualties of martial law in Poland has been the free flow of information between Polish scientists and their Western colleagues. With the total severance of telecommunications, and the postal service considerably delayed by censorship, it has been difficult, if not impossible, for scholarly contacts to be maintained. Moreover, reports in the Western media of protest strikes in the universities and institutes of the Academy of Sciences have aroused considerable anxiety among scientists abroad as to what exactly is happening to their Polish colleagues.

The main source of information has been the lists of internees appearing from time to time via official or unofficial channels. The first list - issued by the Military Council for National Salvation was clearly erroneous; it included several names of people who were actually outside Poland when martial law was declared, such as the young chemist, Miroslaw Chojecki, who became active in the underground press after his dismissal from the Swierk nuclear research institute in 1977. Later lists, received through church channels, though fuller, are still far from complete, and evidence of a colleague's being at liberty is, by and large, negative, and deduced from the absence of his or her name on the lists to date.

Only in a few cases, like that of the 101 intellectuals who signed a letter to the Sejm (parliament) calling for an end to military rule, or the published list of academics called in for consultations with General Jaruzelski in December, is there positive evidence.

A number of scientists have been approaching Polish embassies and consulates to enquire after their colleagues. In the case of known activists, such as the mathematical logician Dr Janusz Onyszkiewicz, a presidium member of the Mazowsze (Warsaw area) branch of Solidarity, or the economist Dr Bronislaw Geremek, one of Solidarity's chief "advisers", such enquiries were initially met by suggestions that if a job could be found for them abroad, the Polish authorities would not refuse an exit visa. Following General Jaruzelski's assurance in the Sejm on 25 January that no internee would be deported from Poland, such proposals have been dropped. Nevertheless, enquiries at consulates do not proceed smoothly - officials are unwilling to discuss "rumours" — even to deny them.

On the facing page we print some extracts from such a conversation, lasting several hours, between Dr Wilfred Hodges and Dr Derrick of the British Logic Colloquium and the Polish Chargé d'Affaires Mr Gorajewski and Scientific Counsellor Mr S. Wojtaszek at the Polish embassy in London.

Vera Rich

Diplomatic conversations

What follows is an extract from a record by Dr Wilfred Hodges, of the British Logic Colloquium, and officials of the Polish Embassy in London.

Question: In his statement of 13 December 1981, General Jaruzelski said: "Our nation has enough strength and wisdom to deploy an efficient, democratic system of socialist rule. In such a system military forces will be able to stay at their proper place — in the barracks." On the other hand we have heard that some university buildings in Poland are now being used as barracks. . . Answer: Where have you heard that university buildings are being used as barracks? This is sheer rumour and we do not answer rumours.

Question: In the same statement, General Jaruzelski said: "The full list of those interned will be published." When?

Answer: Sixty-three names were published soon after 13 December, and further names have been given since on Warsaw Radio. In any case, out of the 5,906 people interned, 839 have already been released.

Question: It is reported that Solidarity members are being required to sign a "loyalty pledge" dissociating themselves from Solidarity. Can you please tell us the wording of this pledge, and what the penalty will be for those who refuse to sign? Answer: In Poland some state administrators have always been required to sign a statement of loyalty. This is nothing new, and we have heard nothing about any change in the text of the statement. As for other people being asked to sign it, and what may happen to them if they refuse, we have no sources of information apart from the British press. We have never heard mention of anybody being asked to sign a pledge which mentioned Solidarity.

Question: Will all academics who are released from internment without facing criminal charges be allowed to go back to the jobs which they held before 13 December 1981?

Answer: We don't know, because we don't know about the loyalty pledge.

Question: We have heard that the following logicians have been interned: Konrad Bieliński (Warsaw) in Biatoteka; Janusz Onyszkiewicz (Warsaw) in Strzeblinek; Marian Srebrny (Warsaw) in Biatoteka; Jan Waszkiewicz (Wrocław); Andrzej Wroński (Krakow). Can you confirm this information?

Answer: We have no list of internees. We notice that a high proportion of the people you mention were in KOR (Workers' Defence Committee). Do you have any contacts in Poland other than these people? «Answer: Yes, many.»

Question: Are the academics who are interned being allowed visits by their families? Do they have writing materials

and the use of scientific books and papers? Answer: Family visits to internees are allowed. The internment camps are resort centres, so there are reasonable facilities, but we would hardly suppose the circumstances are conducive to research. The internees get exercise and see the official newspapers. We would assume that an internee can get books and papers from his home by asking a relative to collect them.

Question: Will you allow a British logician to visit the logicians who are interned, so that he can let us know the conditions in which they are kept, and so that he can pass on to us any requests from them?

Answer: All visas issued before 13 December 1981 were automatically cancelled when martial law was imposed. The present regulations are that if anybody applies to us for a visa, he has to state which organization in Poland is supporting his visit, and then we forward the application to Warsaw for this information to be checked. A British logician could certainly apply to us, but unless he could say that, for example, the Polish Academy of Sciences was inviting him, we suppose that his request would be refused.

Question: If British logicians give you letters (either in English or in Polish) addressed to logicians interned in Poland, will you guarantee that these letters will be delivered, and that the internees' replies will be delivered to us?

Answer: Mail is allowed through now, both within Poland and between Poland and the West. But all mail between Poland and the West is subject to censorship. At a time of crisis, the bureaucrats who operate the censorship are not going to make fine distinctions; if anything doubtful comes past them, they are just going to say no. But we expect that things will get gradually better. If you want to get in touch with internees, try writing to their families.

Question: New regulations for the Polish universities have recently been announced. Are these new regulations permanent, or do they automatically end when the present emergency ends?

Answer: New regulations for the universities were under discussion before 13 December and a new bill was before parliament, but martial law prevented it from being enacted. Since it was necessary to reopen the universities somehow, we reverted to the regulations based on the 1952 law. But this is a temporary situation, and new laws on the universities will be passed as soon as possible.

Question: Which items of academic and scholarly work are to be censored? Will lectures in the universities, and letters to colleagues abroad, be censored?

Answer: Academic censorship is now the same is it was in the 1960s.

Question: After the present emergency, will scholars who are invited to visit universities or attend conferences abroad be allowed to travel outside Poland, or will permission be granted only to those who have the correct political attitude?

Answer: Even in the present emergency, some Polish scholars are leaving Poland to visit abroad. If a particular employer in Poland asks for permission for one of his employees to travel to the West, he can certainly apply, and in principle he might get permission. But visas issued before 13 December were automatically cancelled at the imposition of martial law. If there are one or two Polish scholars that you would like to have visit you, please do apply. For example, the Polish Cultural Institute in London would very likely be willing to bring over one or two Polish scholars for a meeting to be held at the institute.

Question: In 1980 the authorities in Prague cancelled a major international conference of the Association for Symbolic Logic five weeks before it was due to take place, and no clear reason has yet been given for the cancellation. Already one philosophical exchange between Oxford University and the Polish Academy of Sciences in Warsaw has been postponed by the British Academy as a result of the military rule in Poland. In this climate, are the Polish authorities aware what harm would be done to East-West scientific cooperation if the International Congress of Mathematicians, due to meet in Warsaw in August, had to be cancelled or moved as a result of the situation in Poland?

Answer: We shall try to get facts about any conferences you ask us about. In particular we shall ask whether the Polish authorities are still planning for the following conferences to go ahead: Conference in Functional Analysis, Stefan Banach Institute in Warsaw, February 1982; International Congress of Mathematicians, Warsaw, August 1982.

- •Mr Gorajewski and Mr Wojtaszek made a number of other points, including the following: (1) The Polish authorities had no option but to impose martial law, in order to protect Poland's economic links with the other countries in Eastern Europe. (2) By writing to the British Foreign Office to complain about the internal affairs of Poland, the British Logic Colloquium has violated the Helsinki Accords.
- •On receiving a copy of the above summarized answers, Mr Wojtaszek wrote: "Since many of the answers have been significantly misquoted and/or taken out of context, it would at least be fair to say that you, and you alone, might accept responsibility for the interpretations you made and which are often in sharp contrast with the contents of the answers you received."

ORRESP NIDENCE

Back to Nature

SIR — The article "Mental stress given environmental status" (Nature 21 January, p.179) shows an extreme ignorance of the dangers of ionizing radiation. Stating that there was "no significant extra radiation exposure to individuals" after the Three Mile Island incident implies the existence of insignificant levels of radiation. Not true! Any amount of radiation will produce a proportionate increase in mutation rates in exposed genes. There is no safe level of radiation, only less harmful levels.

Your leading article (Nature 21 January, p.177) regarding the recent US Court of Appeals ruling that psychological effects must be considered when making an environmental impact statement is speckled with specious statements and biased comments. First, it is ridiculous to presume that under this ruling "hydroelectric schemes of all kinds would quickly be stopped". Nuclear projects are fundamentally more dangerous than hydroelectric facilities. Dams do not increase mutation rates; dams do not remain mutagenic for thousands of years. Second, you lament that "most defence projects and all nuclear projects (would be quickly be stopped)". These structures should exist to serve the majority of the people of this country (not the armament industry or the utilities), and if the people feel traumatized by these projects to the extent of working to prevent their construction, then the people should have the power to say No. You feel that this result "would be a nonsense" and that "environmentalists (now) have a licence to do irreparable damage". I fail to see how allowing people to shape the nature of their environment can be "nonsense" or irreparably damaging to anything but the armament and utility industries. Finally, your choice of adjectives suggests an empathy with industry, not the environment. Metropolitan Edison is not "luckless". Luck has nothing to do with the scientifically and economically unsound decision to build nuclear power plants. Please, consider diverting your sympathy from the nuclear industry to your namesake: Nature.

Astronomical flaw

Sir — Can someone explain why creationists seem to reserve their attention for biologists and the theory of evolution and ignore astronomers?

As I understand it, the creationists reject the theory of evolution because that is not how things are described in the Book of Genesis. Yet that book clearly states that the Earth, complete with flowering plants, was created before the Sun (Genesis 1, v.9-19).

I am no astronomer but I should have thought that that was incompatible with any currently accepted theories of planet formation.

However, I have not seen the point raised in any creationist argument.

Are some parts of *Genesis* more historically true than others? If so how does one tell which is which?

I.P. FREEMAN

Beijing duck now

SIR — As reported in four articles in *Nature* of 3 December 1981¹, in 1980 foreign scientists were allowed entry into Tibet for the first time since the Chinese military takeover of that country in 1950. This opening of Tibet for scientific study is highly welcome. However, the Chinese usage of special Chinese spellings of Tibetan words (as also used in the *Nature* articles) merits comment.

Tibetan is a language quite unrelated to Chinese and has, in contrast to the latter, an alphabet. This can be very accurately transcribed using roman characters. However, Tibetan spelling being fairly complex, it is often preferred to spell Tibetan names the way they sound, so that an English-speaking reader can immediately pronounce the names with a fair degree of accuracy.

Unfortunately the Chinese now have extended the pinyin system also to Tibetan words. This system was created to romanize Chinese words in a unified manner, and it is the official system in use in the People's Republic of China today. (Thus Peking is now spelt Beijing.)

Since pinyin was constructed for the Chinese language, it can be used for Tibetan words only by a concomitant loss of accuracy. This is partly because of the system's inherent adaptation to the Chinese language, and partly because pinyin spelling is the result of a foreigner (Chinese) writing in roman letters in an artificial system what he thinks Tibetan words sound like. This filtering necessarily introduces a considerable degree of distortion.

Furthermore, pinyin replaces well-known spellings with strange ones. For instance, the second largest city of Tibet, traditionally spelt Sigatse, becomes Xigaze. Since "Shigatse" very accurately reflects the Tibetan pronunciation and is the established way of spelling the name, nothing is gained by the substitution. The same goes for changes of other words into pinyin.

Finally the Chinese system introduces a further confusion in that other Tibetan-speaking areas, such as northern India and Nepal, Bhutan, Sikkim and Ladakh, do not use this system. Thus the danger ensues that two parallel romanizations will be used for the same words.

It is to be hoped that intensified research contacts regarding Tibet can be established in the future between the West and China, and ultimately also Tibetan scientists. The question of the spelling of Tibetan words would then become of increased importance.

Missed the mark?

SIR — Jon Marks' letter (*Nature* 28 January, p.276) shows a misunderstanding of the intent and meaning of the Bible. The Bible is a collection of writings from various peoples and times, all focusing upon their experience of God. It is not designed to be a scientific textbook. It is wrapped within the time, culture and world outlook of its authors (what literature is not?) and yet succeeds in breaking out of those limitations to accomplish its purpose and point men to God's active concern in their lives. In this respect, Dr

Marks is just as guilty as those he criticizes in quoting the Bible in a way that is incompatible with its primary intent. He does it for ridicule; his opponents for scientific reductionism; but is either legitimate?

The way in which biblical quotations are used often tells us more about the person quoting than the subject under discussion. This is clearly evidenced by the way in which Leviticus 11:19 and Luke 23:43 were utilized. In his reference to the bat being categorized as a bird. Dr Marks has not discerned the culturally bound attempts of the writer of Leviticus to make sense out of the world based upon the evidence as he understood it. We should not stand in judgement of such attempts simply because of our more privileged information. One wonders if some of our scientific "certainties" will pass the scrutiny of scientists in four thousand years' time. Again, an understanding of the relationship between Jesus' death and the Kingdom of God in the world would prevent misinterpretation of Luke 23:43. "Paradise" as an image of the Kingdom of God is inseparably linked within the New Testament of Jesus' death and resurrection. That crucial phase of Jesus' life was beginning to take place on that very day ("today"). If the creationists and evolutionists would take time actively to study the Bible then such matters would not come to trial.

The Bible does see the design and diversity of nature as pointing to a Creator, but does not demand a fundamentalist, creationist interpretation of *Genesis* 1. Even Creationism should allow an element of evolution. Nature suggests that the Creator builds one design from another to achieve increasing complexity.

Furthermore, the Bible clearly indicates that God is still creating. The Thomistic argument of design pointing to the Creator is admittedly not without its difficulties - but equally so is the argument from chaos to non-creator. Both fall under the same criticisms and fail to see that either is dependent upon faith in establishing the relationship between data and that to which data point. Evolutionary theory has for too long been six feet above contradiction. In this context the challenges enshrined in neo-Lamarckism, punctuated equilibria theory and cladistics should be welcomed. Evolution should be subjected to the same scrutiny as any other theory, and should be capable of modification or replacement. Indeed when a theory loses its ability to be superseded it becomes a dogma.

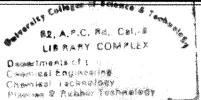

The evolutionary process, when extrapolated beyond its scientific confines, can be used to justify any number of monstrous evils, as history only too well documents. We must admit that man is a creature whose life is not encapsulated within empirical study alone but contains a drive which pushes him Godwards. Man can only be understood as making progress in so far as the touch of God is able to continue to direct him. The way forward to us seems to be commitment to scientific investigation combined with dedicated and honest study of the Bible.

NEWS AND VIEWS

Processes of gene duplication

from Alec J. Jeffreys and Stephen Harris

GENE DUPLICATION is probably one of the most important mechanisms for generating new genes and novel biochemical functions during evolution. Evidence for this process is seen in the numerous families of related proteins specified by the genomes of higher organisms. Through the use of recombinant DNA methods to study the arrangement of duplicated genes, two basic patterns of gene family organization have emerged: linked clusters of related genes in which individual genes are separated by long regions of non-coding DNA, and dispersed families in which individual members are scattered over widely separated chromosome locations.

The globin family in mammals neatly illustrates both modes of organization, with two unlinked gene clusters, one specifying the α -related globins and the other the β -globins. The family has recently been the subject of intensive research which has attempted to discern the molecular mechanisms that lead to the tandem duplication of a single gene and to the dispersal of genes to remote locations.

The human β -globin gene cluster contains five active globin genes arranged in the order ε - ^{G}y - ^{A}y - δ - β , together with two pseudogenes and extensive tracts of DNA between the genes I . The two closely related fetal genes (^{G}y and ^{A}y) have clearly arisen by a recent duplication within the cluster. Recently, Smithies and colleagues have sequenced over 11 kilobases (kb) of DNA encompassing the fetal globin genes, and have shown that the region contains a large (5 kb) tandem duplication. Each duplicate has a γ -globin gene embedded within it $^{2-4}$.

How did this duplication of a relatively large chromsome segment arise? A clue comes from the existence of a short directly repeated DNA segment (r) at each end of the repeat, giving an organization r-Gy-r-Ay-r (ref.3). While the authors suggest several models to account for this arrangement, the simplest involves mispairing and unequal crossing-over at meiosis between the repeated elements present in an ancestral r-y-r DNA segment

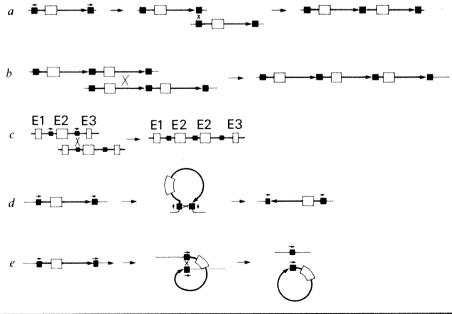

(Fig.1a). If this is correct, then the size of the duplicated region would have been initially determined by the (fortuitous?) spacing of repetitive elements near the non-duplicated locus. The prevalence of families of short repetitive elements scattered throughout the mammalian genome would suggest that large block duplications might occur commonly, though the proportion of these that would be fixed in evolution is not known.

According to the locations of the repetitive elements involved in unequal crossing-over, more than one gene could be included within the duplicated block. A fascinating example has been found by Cleary and colleagues in the β -globin gene cluster of the goat⁵. The adult $^{A}\beta$ -globin gene is preceded by a pseudogene $\psi^{Z}\beta$, and similarly the $^{C}\beta$ -globin gene coding preadult globin is linked to another closely homologous pseudogene, $\psi^{X}\beta$. The authors suggest that this arrangement has probably evolved by two successive duplications of a single ancestral β -globin gene. The first duplication, accompanied

by silencing of one duplicate, gave a $\psi\beta$ - β pair, and more recently a larger block duplication of this pair generated the $\psi^Z\beta$ - $^{A}\beta$ and $\psi^X\beta$ - $^{C}\beta$ pairs. The length of the block duplication and the presence of repetitive elements flanking the blocks have not yet been determined.

By comparing duplicated DNA segments it is possible to learn something of the modes by which genic and intergenic DNA diverge in evolution. The Gy-Ayglobin gene duplication provides an excellent example. Phylogenetic comparisons of primate β -globin gene clusters show that the duplication probably occurred about 20-40 million years ago in the lineage leading to Old World monkeys. apes and man⁶. Since then, the sequences of most of the two block repeats have diverged about 14 per cent from each other and have also accumulated numerous very small deletions and insertions2-4. Surprisingly, one substantial region (1,500 base pairs long) including most of the Gy globin gene is more than 99 per cent identical in sequence to the corresponding

Fig. 1 Consequences of recombination between dispersed repeated DNA elements. Short repeated DNA sequences (solid boxes) are shown either near genes (open boxes in a, b, d and e) or within intervening sequences separating the exons (c) of one gene. In d, the short sequences are orientated in opposite directions.

Alec J. Jeffreys and Stephen Harris are in the Department of Genetics, University of Leicester, University Road, Leicester LEI 7RH.

region around the Ay-globin gene. Since it is difficult to see how selection could have led to this remarkable homology, the authors suggest that the region has been homogenized by gene conversion between misaligned y-globin repeats very recently in evolution^{2,3}. Gene conversion between related DNA sequences seems common in evolution and appears to operate not only within protein-coding gene families but also in middle and highly repetitive DNA sequences. It may serve to maintain sequence homogeneity within a family (see ref.7). It is interesting that the end of the converted region in the y-locus, as well as the end of a long homology block around the duplicated α -globin gene in man, contains the simple sequence (TG),2,8. Since this sequence can, in principle, adopt a left-handed helical configuration, the authors suggest that such an unusual localized structure in DNA might be involved in initiating the related processes of recombination and gene conversion.

In the goat, the duplicated loci each containing a $\omega \beta$ - β -globin gene pair provide an interesting test for sequence divergence of homologous pseudogenes. When homologous functional genes are compared with each other, base substitutions are found preferentially in flanking sequences, introns and third codon positions in exons, presumably because substitutions that alter the amino acid sequence of the protein are more likely to be eliminated by selection. In contrast, the goat $\psi^{X}\beta$ and $\psi^{Z}\beta$ sequences show throughout a much more uniform divergence⁵, consistent with the idea that pseudogenes are the non-functional relics of excessive gene duplication (see ref.9). However, it is worth noting that what is a pseudogene in one species can be a functional gene in another; the minor adult δ-globin gene is active in man, apes and New World monkeys but has been silenced independently in Old World monkeys¹⁰ and lemurs11.

The presence of small repetitive elements and tandem repeats in gene clusters can lead to other shifts in gene organization. Long tandem repeats provide excellent targets for unequal crossing-over, and can rapidly amplify to give arrays of three, four or many more closely related genes (Fig. 1b), such as those found in ribosomal DNA clusters, histone gene clusters and satellite DNAs. Oppositely orientated short repeats can cause localized inversions (Fig. 1d) and may have been responsible for one form of thalassaemia in man12. Dispersed repetitive elements can also exist in introns, and recombination between direct repeats in different introns (Fig. 1c) could lead to an internally duplicated intron/exon arrangement that could be further amplified by the mechanism in Fig.1b. Strong evidence for internal duplication has been found in IgC_H¹³, ovalbumin¹⁴, ovomucoid15 and a-fetoprotein¹⁶ genes, and further amplification is probably responsible for

the very highly split nature of the a-collagen gene¹⁷.

Dispersed repeated elements could also lead to excision of genes via intrachromosomal recombination (Fig. 1e). The excised circle could reintegrate elsewhere in the genome by homologous recombination with another member of the repeated DNA family. While this process might contribute to the dispersal of gene clusters without duplication, other mechanisms involving gene duplication also seem to operate. The simplest processes entail chromosome duplication, polyploidization and chromosomal translocation. A more subtle and remarkable process that might both duplicate and scatter genes is being unravelled (see A.J. Flavell Nature, News & Views 295, 370; 1982; and ref. 18). A mouse a-globin pseudogene with two remarkable properties has been found: first, it has escaped the parent gene cluster; and second, it appears to have been processed to remove introns, as though the gene had passed through an RNA splicing stage. The discovery of retrovirus-like sequences near this processed wa3-globin gene in the mouse genome suggests that the original gene was somehow kidnapped by a proretrovirus and transposed via spliced retroviral RNA.

Clearly, gene clusters are inherently unstable entities that can expand, contract and disperse during the course of evolution. Of all the possible shifts in arrangement, natural selection will eliminate the unfavourable, leaving neutral and advantageous changes to be fixed in evolution. Although it is difficult to distinguish between neutral and selective changes, some degree of adaptive changes has accompanied the Gy-Ay-globin gene duplication in man and the AB-CB duplication in the goat, in which the duplicated genes tend to be expressed at different stages of development. The molecular basis for these adaptive changes is as yet completely unknown, and is unlikely to become clear from DNA sequencing data alone.

Parasite-induced pathology

from F.E.G. Cox

INFECTIONS with parasites are characteristically long and chronic and the resulting diseases involve diverse pathological mechanisms. The damage caused is vastly in excess of the expected local reactions to the parasites themselves and appears out of all proportion to their size. A recent colloquium* attempted to assess some of the mechanisms involved.

For many years it has been believed that the prolonged but misdirected immune responses of the host are largely responsible for the pathological changes observed. In some infections this is no doubt the case; in schistosomiasis, for example, the adult worm, coated with host antigens, is immunologically invisible but the eggs lodged in various tissues elicit classical delayed-type hypersensitivity reactions which result in the formation of granulomas, the deposition of collagen and eventually fibrosis that is often fatal. This is not, however, the whole story.

Schistosome egg antigens are themselves able to stimulate the production of collagen in a manner similar to that seen in many diseases — in particular silicosis, in which silicon compounds stimulate macrophages to produce factors that activate fibroblasts to produce collagen and eventually fibrosis. The collagen in schistosome granulomas is a normal host component produced in the liver from arginine which is used for the synthesis of proline, an essential prerequisite for collagen formation. Normally, proline is degraded but this degradation is inhibited within schistosome-induced granulomas. Collagenolytic activity is restored after the infection has been cured. Thus the major pathological lesion in schistosomiasis can be partially explained in terms of parasite by-products that influence the normal physiological activities of the host. The egg antigens also seem to be directly hepatotoxic and the granulomas actually protect the liver cells from damage, which suggests that this pathological reaction, induced by either or both egg antigens or immunological reactions to egg antigens, may have some protective effect not yet clearly understood. The clearance of foreign immune complexes is also inhibited

^{*}An international colloquium on the pathogenesis of disease induced by parasites was held at the Prince Leopold Institute of Tropical Medicine, Antwerp, on Leopoid Institute of Tropical Medicine, Aniwerp, on 11-13 December 1981. The proceedings, From Parasitic Infection to Parasitic Disease, will be published by S. Karger (Basel) in the Series Contributions to Microbiology and Immunology.

F.E.G. Cox is Professor of Zoology at King's College, University of London, The Strand, London WC2R 2LS.

in schistosome-infected animals; this is due not simply to changes in circulation resulting from the granuloma formation, but to the presence of adult worms. The parasites themselves are thus responsible to a large extent for the pathology associated with schistosomiasis.

In fascioliasis it is now clear that excretory products from the adult flukes have a direct deleterious effect on the liver cells of the host by blocking mitochondrial ATP synthesis. In African trypanosomiasis, the trypanosomes catabolize aromatic amino acids and not only deplete the host of essential amino acids but also produce toxic by-products from them. The main catabolites of tryptophan, for example, bring about major physiological changes including the induction of a state of coma similar to that seen in human sleeping sickness and those of phenylalanine inhibit gluconeogenesis and mitochondrial activity. In animal trypanosomiasis, extravascular parasites cause cellular infiltration and necrosis, particularly in the heart and nervous system.

Cardiac and nervous tissue are also involved in the pathology of malaria, and in rodent models, endomyocardial fibrosis following the passage of macrophages, polymorphs and fibroblasts through the endothelial layer has been demonstrated after drug cure and some brain lesions appear to be caused by the compression of capillaries by the accumulation of fluid in pericapillary glial cells. These observations indicate that physiological changes may contribute to the pathology of malaria but other evidence suggests that immune complexes characteristic of malaria simply indicate brain damage and do not necessarily cause it.

The overall conclusion is that we now know enough about the pathology of parasitic infections to say that physical and physiological changes may be as important as, or even more important than, immunologically induced damage. Of particular importance is the realization that certain aspects of the pathology of sickness resemble sleeping phenylketonuria, of schistosomiasis silicosis and of malaria, paraquat poisoning or burns. Our understanding of the pathology of parasitic infections can benefit from progress being made in other fields and should not be considered in isolation. Again, certain techniques devised for parasitological studies such as the injection of Sephadex beads loaded with schistosome egg antigens to induce liver granulomas may be relevant to the investigation of non-parasitological diseases. In this context, it is important that parasitological studies have had a leading role in our understanding of the part played by eosinophils in various infections. As eosinophils are involved endomyocardial fibrosis it may well be that the role of these cells, and the basic proteins they produce, will become more clearly

defined as a result of further investigations using parasites.

Eosinophils are not the only cells to be incriminated in the pathology of parasitic infections — macrophages and their products seem to play a central part in many infections. We need to know much more about the activities of these cells before we can say that we understand the basis of the pathology of parasitic infections let alone know enough to ameliorate the effects. Nevertheless, there is no doubt that pathology is about to emerge from years of comparative neglect when it has taken second place to immunology and will become one of the most important and rapidly developing aspects of parasitology.

A new approach to the determination of absolute configuration

from W. Jones

CHIRALITY plays an important part in chemistry and lies at the heart of many important biological processes. But under what circumstances is one kind of handedness chosen? Is a particular molecular glove intended for the right or the left hand? And even more fundamental, from which side of the mirror do we observe? These questions have been asked ever since Pasteur's classical experiment in 1848 resolved the two optical isomers of sodium ammonium tartrate¹.

Not withstanding Pasteur's breakthrough the question of absolute configuration still remained, it being necessary to make an arbitrary assignment (either right or left) to one particular molecule and refer all others to this. No further progress was made until 1949 when Bijovet proposed the use of anomalous dispersion of X rays2. His proposal rested on the fact that for an appropriate wavelength of probing X-ray beam a non-centrosymmetric crystal structure will lead to slight differences in scattering intensities from certain planes, in violation of Friedel's law. Experimental proof followed and since then the absolute configuration of over 500 optically active compounds has been determined by this method³. Apart from two other techniques³, one rather esoteric and the other somewhat restricted, but which incidentally confirm assignments based on Bijvoet's proposal, no other general methods have been available by which absolute handedness may be

W. Jones is a Fellow of Sidney Sussex College and is in the Department of Physical Chemistry, University of Cambridge, Lensfield Road, Cambridge CB2 1EP. determined. In this issue of *Nature* (p.21 & p.27) however, Leiserowitz and his colleages describe a new approach whereby absolute configuration can be deduced from a study of the crystal habit which a collection of the chiral molecules adopt. The approach has its origins in the reactivity of organic molecules within crystalline solids.

The course of many solid-state reactions is crucially controlled by the arrangement of the molecules within the crystal lattice4-6. Furthermore, any molecular asymmetry is manifested in the solid state by the manner in which the molecules pack in the highly ordered three-dimensional arrangement of the crystal. If both types of optical isomer are taken up within a crystal then symmetry operations which 'translate' a right-handed molecule into its left-handed counterpart (that is, a mirror plane) must be present. If such symmetry features are absent then only molecules of one handedness may be incorporated and the space group (that which describes the three-dimensional arrangement) is said to be chiral. Furthermore — and herein lies its strength - for any solid-state reaction which proceeds under so-called lattice control this chirality will be transferred to the product and only one type of optically active isomer will be formed.

By this method absolute asymmetric syntheses have been accomplished?, with the chirality of the product determined by the absolute configuration of the parent crystal. The next stage, however, is to enquire whether there exists a feedback mechanism whereby 'seeding' of the mother liquor with product of one (say D) chirality will induce preferential crystallization such that even more of the D isomer may be formed. The results indicate that the addition of D product invariably leads to growth whereby L crystals (and subsequently L product) are in excess—the inversion rule.

Leiserowitz et al. show that this occurs because the D-product isomer is preferentially absorbed on growing D-reactant crystals and impedes or considerably modifies their growth. In the absence of optically active impurities, perfect crystals of D and L form are obtained from solution. After addition of a small amount of D impurity only L crystals with perfect morphology emerge. But the full implication of these observations lies in the possibility of determining absolute configuration. For if one uses 'impurity' molecules with identified groupings and observes which crystal face or faces are modified with respect to particular directions within the crystal one has a method of obtaining absolute configuration. This argument (see p.27) leads to the emergence of a new and potentially powerful technique capable of dealing with racemic crystals and which relies only on observation of crystal morphology and very elementary X-ray diffraction measurements. The prospects are exciting.

0028-0836/82/090011-02\$01.00

Not only may we find here a convenient method of ascertaining absolute configuration, but we may also reap other practical benefit from the ability, which their work presents, of engineering the morphology of crystals.

C-reactive protein and the acute phase response

from M. B. Pepys

THE acute phase response consists of the increased production of a number of plasma proteins which occurs following most forms of tissue injury, inflammation. infection and malignant neoplasia. C-reactive protein (CRP), so-called because it precipitates pneumococcal somatic C polysaccharide, was the first 'acute phase protein' to be identified. It was discovered in O.T. Avery's laboratory at the hospital of the Rockefeller Institute and was one of three fundamental contributions to biology to emanate from there, the others being the identification of DNA as the genetic material in pneumococci and the establishment of the role of polysaccharides as antigens.

There has lately been much progress in the characterization of CRP, of other acute phase proteins and the mechanisms underlying the acute phase response in general. These advances were marked recently by the first international meeting* to be held on the subject.

Many circulating proteinase inhibitors, complement, coagulation and transport proteins have been shown to behave as acute phase reactants. The general nature of the acute phase response, its stimulation by many forms of cell injury, and its occurrence in all homoiothermic species, suggest that it fulfills a beneficial function. With respect to CRP this view is supported by the evolutionary conservation of structure and binding reactivity of the CRP

family. CRP of all species binds to phosphorylcholine (PC) residues in the presence of calcium ions and PC-binding proteins homologous with human CRP occur in many vertebrates, including fish, and even in an invertebrate, Limulus polyphemus, the horseshoe crab. A normal human plasma protein, known as serum amyloid P component (SAP) because the molecule is pentagonal in shape and because it is laid down in amyloid deposits, closely resembles CRP in structure with 60-70 per cent homology of amino acid sequence. Homologues of human SAP are also present in all vertebrate classes.

A serious pathological complication of a sustained acute phase response, due to persistent infection or inflammation, is the deposition of amyloid A (AA), an extracellular accumulation of protein fibrils consisting of peptide subunits arranged in an anti-parallel β-pleated sheet. The protein is derived from a serum precursor (SAA) which is apolipoprotein of high-density lipoprotein produced in the acute phase. The trigger molecule initiating synthesis of SAA and other acute phase proteins by liver cells is apparently interleukin-1 (IL1), a peptide product of macrophages. IL1 also activates T lymphocytes and is a pyrogen. Its production can be initiated either by direct stimulation of macrophages, for example, with bacterial lipopolysaccharide, or indirectly by mediator(s) released from damaged tissue cells, possibly prostaglandins. The mechanism by which liver cells increase the abundance of mRNA for acute phase proteins in order to provide for their increased synthesis is not yet known. However, the genes for SAA

and for α_1 -acid glycoprotein, another acute phase reactant, have now been cloned and this may provide information on control of synthesis as well as on the structure, functions and evolution of the proteins themselves.

The normal in vivo functions of CRP, SAP and SAA are not yet known. Presumably, for CRP and SAP these are related in some way to their strictly conserved ligand-binding properties. CRP binds preferentially to damaged rather than intact autologous cell membranes and having done so, human CRP activates the complement system; part of its role may be to elicit the inflammation required for resolution and repair. CRP also binds to extrinsic ligands and can thus enhance resistance, for example to pneumococcal infection in mice. In addition to being a normal plasma protein and a constituent of amyloid deposits, SAP or a closely related protein is also a normal tissue protein. It is found in glomerular basement membrane and in association with elastic fibre microfibrils throughout the body. Its role in tissues is not known but it is of interest that aggregated SAP selectively binds fibronectin from whole serum.

Clinical measurements of serum CRP. which, like basic studies of CRP itself, suffered a long period of decline, are now being treated with fresh enthusiasm. Such measurements are useful in screening for organic disease and in monitoring the activity of many inflammatory or necrosing disorders, and are a sensitive test for infection. Although the acute phase response is a non-specific manifestation of tissue injury its precise quantification can provide a valuable aid to the clinician at the bedside.

100 years ago

"Nowhere has the hand of man moulded ground into shapes more strangely contrasted with its natural form than on the site of London. Even as late as the time of Caesar the soil which a large part of it covers can have been little but a vast morass. Below Fulham the river stretched at high tide over the ground that lies on either side of its present channel from the rise of Kensington and Hyde Park to the opposite shores of Peckham and Camberwell. All Pimlico and Westminster to the north to the south all Battersca and Lamberth, all Newington and Kennington, all Bermondsey and Rotherithe, formed a vast lagoon. Near the point where the Lea poured its waters into the Thames, a traveller who was mounting the Thames from the sea saw the first dry land to which his bark could steer. The spot was in fact the extremity of a low line of rising ground which was thrown out from the heights of Hampstead that border the river valley to the north, and which passed over the sites of our Hyde Park and Holborn to thrust itself on the east into the great morass.

^{*&#}x27;C-reactive protein and the plasma protein response to tissue injury', organized by I Kushner, H Gewurz & J E. Volanskis and held at the Barbizon-Plaza Hotel, New York, 21-23 September 1981 under the auspices of the New York Acade Sciences Proceedings to be published in the Annals of the New York Academy of Sciences, 1982

The International Conference on Venus

After Pioneer—good science, bad news

Over the last few years an intense study of the planet Venus has been undertaken following its exploration by spacecraft from the US and the USSR. At a recent meeting* in Palo Alto, every aspect of the planet was discussed. In the six articles that follow, contributors at that meeting survey a selection of the topics covered.

Our nearest planetary neighbour (its orbit has a radius seven-tenths that of the Earth), Venus has a size and mean density only slightly smaller than our own. Regrettably, even the best optical telescopes reveal a disk with an absence of surface features owing to the brightly reflecting clouds that shroud the planet.

It required high-sensitivity radar techniques to pierce the clouds and show that Venus rotates on its axis once every 243 days. Unlike all the other planets except Uranus, this rotation is in the opposite sense to the planet's orbital motion. In fact, this rotation rate ensures that approximately the same face of Venus is turned towards the Earth when the two planets are closest to each other in their orbits. This implies that during the history of the Solar System, Venus has become locked into a rotational near-resonance by the Earth's gravitational influence; Venus must necessarily be axially asymmetric in its mass distribution.

Spectroscopy revealed that the atmosphere consisted mainly of carbon dioxide and that the clouds contained sulphuric acid, while the radar measurements revealed poorly defined large-scale surface features. Several direct measurements of surface conditions were provided by Soviet spacecraft. In 1975 Venera 9 and 10 provided the only surface photographs so far obtained revealing a boulder-strewn terrain. The surface temperature was found to be over 400 °C.

Our perception of Venus underwent a revolution in 1978, however, when several spacecraft reached the planet. One was the Pioneer multiprobe mission, whose five spacecraft entered the atmosphere on 9 December and ceased to send data about two hours after entry. Four of the craft reached the surface, two on the nightside and two on the dayside. A parallel mission was the Pioneer Orbiter, which circles the planet and sends data still. In the same month that Pioneer arrived, two Soviet spacecraft, Venera 11 and 12, reached Venus, both landing a probe on the surface.

*The International Conference on the 'Venus Environment' was held in Palo Alto, California on 1-6 November 1981.

One question that was finally answered by Pioneer concerned Venus's very high surface temperature. Although closer to the Sun, the high reflectivity of the atmosphere should have resulted in a surface temperature lower than that of the Earth. Pioneer confirmed what had been suspected before - that a greenhouse effect was responsible. A carbon dioxide atmosphere would not have supplied the required blanketing effect owing to spectral 'windows' in the IR band, Pioneer showed, however, not only that enough sunlight reached the surface to fuel the effect but also that the small water (~ 0.1 per cent) and sulphur dioxide concentrations could produce enough absorption to close those spectral windows (see the article by Taylor).

Venus is sufficiently similar to the Earth and sufficiently different to provide a fascinating climatalogical laboratory. The planet's very slow rotation rate results in small Coriolis forces that might be predicted to cause less distinct latitudinal effects (such as zoning) than those found on the Earth, let alone the fast-rotating giant planet Jupiter. The absence of oceans releases fluid theoreticians from the complications of land-sea contrasts and corresponding latent heat budgets. Moreover, the planet's rotation axis is only 3° removed from the perpendicular to its orbital plane, compared with the Earth's 23°. Thus seasonal effects are virtually absent on the planet. Another difference arising from the slow rotation rate, of course, is the very slow passage of solar heating over the surface.

The picture that has emerged is discussed in detail in three of the following articles. Briefly, the temperature gradients from equator to poles are very small owing to an efficient single circulation cell in each hemisphere, which transports heat from the equator to the poles. In fact, the gradients are larger than expected. Moreover, the massive atmosphere (ninety times the mass of the Earth's), with its consequent high thermal inertia, had been expected to smooth out any longitudinal (day-night) thermal contrasts in the lower atmosphere. That this is not the case has been attributed to the action of eddy and wave transport.

The role of atmospheric waves is also thought to be crucial to understanding the high cloud velocities. The patterns are observed to super-rotate about the planet in four days, at a speed of about 100 m s⁻¹.

Above and below the three main cloud layers (which are found to concentrate at heights between 45 and 70 km) the atmosphere is relatively calm. Theorists have concluded that the high momentum is pumped into this layer by waves and eddies from the lower atmosphere, as discussed by Elson below.

The atmospheric circulation cells are concentrated at cloud heights, where much of the solar heat is absorbed. The clouds must play an important part in atmospheric energetics. It should be remembered, however, that these clouds are not the result of condensation from a vapour transported upwards by convection, as is often the case on Earth. (Pioneer found Venus's lower atmosphere to be surprisingly stable.) As Knollenberg discusses, they are the long-lived products of the atmospheric photochemistry of Venus. They have been compared with the urban 'brown clouds' which are only gradually removed from our atmosphere by rain.

Venus also differs from the Earth in that it appears to lack a magnetic field. This has important implications for the uppermost atmosphere. A strong magnetic field, as on Earth, would interact with the magnetic plasma (the solar wind) that impinges on all the planets, and deflect it. On Venus the ionized upper atmosphere on the dayside faces the wind unprotected, with the result that energy from solar disturbances can be more directly dumped from interplanetary space into the upper atmosphere. Relevant processes are discussed in more detail in the articles by Nagy and Brace and by Cloutier and Russell.

The orbiting radar of Pioneer has mapped the surface topography. These observations, combined with measurements of the planet's gravitational field, have led to the conclusion that Venus's crust is considerably thicker than the Earth's and is not broken up into 'plates' (see article by McGill). The heat from the planetary interior appears to be reaching the surface primarily beneath two elevated regions, the Beta Regio and the Aphrodite Terra highlands. The detection of volcanic land forms and radar signatures comparable with those observed from lava flows on Earth has led some to believe that these regions are currently volcanically active. This belief is supported by the discovery that the sources of lightning on Venus appear to be concentrated in these two 'volcanic' regions, suggesting that arcing

within volcanic dust clouds (as happened in the Mt St Helens eruption) may be occurring.

One of the most surprising results from the Pioneer and Venera measurements was that the abundances of non-radiogenic rare gases such as 36Ar were much higher than on the Earth. In fact, the values decrease in order-of-magnitude steps from Venus to Earth to Mars. The atmospheric abundances of these non-reactive gases result from three possible processes: (1) accretion during planetary formation from the solar nebula; (2) accretion from planetary bombardment by asteroids and comets; and (3) outgassing from planetary interiors. None of these processes would be expected to result in the observed distribution. Resolution of this problem is some way off, and is not helped by the fact

that different rare gases appear to be telling different stories.

What of the future? the next major advances in Venus science will hopefully come from the USSR. Two more Venera craft were launched at the end of last year, equipped with landers aimed at the Beta Regio area. Two further spacecraft are expected to be launched in 1984 or 1985, which will release two landers onto Venus before proceeding to Comet Halley. Meanwhile, the reduced NASA budget is impeding the further analysis of planetary data. In view of the stimulating results from Venus, such a situation can most politely be described as tragic.

Geology and geophysics

from George E. McGill

Even though Venus is the most Earth-like object in the Solar System, there are important geological and geophysical differences, the most notable being the high pressure and temperature of the atmosphere (~96 bar and 740K at the median elevation)¹, and the very low abundance of water². These characteristics imply that at shallow depths, Venus is hotter and drier than Earth. Nevertheless, recent models of thermal evolution predict temperatures very similar to those on Earth in mantle regions subject to solid-state convection3-5. The high temperature of the shallow interior implies a more buoyant lithosphere than on Earth for several reasons^{6,7}, some of which depend critically on the per cent of bound H2O in the upper mantle, a quantity that strongly influences

lithosphere thickness⁸ but which remains unknown.

Pioneer Venus radar altimetry has been carried out over 93 per cent of the surface. In contrast to the bimodal distribution of surface altitude of Earth, the Venus topographical spectrum is markedly unimodal (Fig.1), with 60 per cent of the known surface within 500 m of the median radius9. The dual level of Earth topography results from (1) the contrasting densities of the two types of crustal rocks, continental and oceanic (the continental 'sial' and the denser oceanic 'sima' composed predominantly of silica and, respectively, aluminium and magnesium); (2) the Earth's plate tectonic activity, which continually creates thin, low-standing sima while sweeping thicker, higher-standing

sial into clumps; and (3) the presence of oceans that trap most sediment close to the continents. If Venus has differentiated a significant amount of sial, then the strongly unimodal elevation spectrum implies that horizontal transport of the lithosphere due to plate tectonics, if present at all, must be even slower than the presumably very slow rates of erosion and sediment transport expected on a planet with no hydrologic cycle.

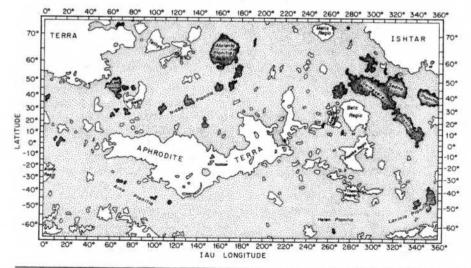

Crater-like forms occur on the venerean lowlands¹⁰; some of these may be of impact origin, some probably are volcanic, but most are enigmatic. The areally limited elevated regions include many tectonically interesting topographical features: large, straight to arcuate troughs up to 2,500 km long, round to irregular depressions, linear zones of 'pitted and hilly' terrain, and large massifs. Most of these features are associated with three regions: Aphrodite Terra, Ishtar Terra and Beta Regio (Fig. 2).

The largest elevated area is Aphrodite. In its eastern portion are several major arcuate troughs with flanking ridges⁹ and a moderately elevated terrain characterized by irregular depressions and hills (Fig. 3). The entire system of pitted and hilly terrain and troughs defines a linear zone that is radar rough at both centimetre and metre scales¹⁰ and which is almost certainly of tectonic origin¹¹⁻¹³.

Ishtar Terra includes a large plateau (Lakshmi Planum) flanked by narrow linear mountain belts along its western and northwestern margins, and by a large massif (Maxwell Montes) along its eastern

George E. McGill is Head of the Department of Geology and Geography, University of Massachussets, Amherst, Massachusetts 01002.

Fig. 2 Major topographical regions of Venus. Elevations >1 km above median clear; elevations within 1 km of median in light stipple; elevations >1 km below median in heavy stipple. Mercator projection greatly exaggerates the size of Ishtar Terra, which actually includes about half as much area as Aphrodite Terra.

margin which contains a point 11 km above median — the highest so far discovered on Venus. On the flanks of this massif are several depressions, including a circular region smoother at centimetre scale than its surroundings14. The depressions are probably volcanic in origin¹⁰. Two larger but much more irregular depressions occur on Lakshmi Planum. Their obvious noncircularity and their association with large 'canyons' extending into the plateau from its southern rim constitute strong evidence that they are of tectonic or volcanic origin rather than due to meteorite impact 12,13. The general association of a large plateau. volcanic and tectonic depressions, and linear mountain belts has led some workers to suggest that Ishtar is the best candidate for a true continent on Venus^{4,5}.

Beta Regio appears to be a domical uplift with a medial rift, and with at least one large shield volcano built on it14,15. This association, together with some additional topographical details, lead naturally to the inference that the Beta Regio area is analogous to a continental rift system, such as in East Africa 12,13,16.

Despite the presence of some landforms suggesting active tectonics, there is no evidence of a global system of spreading ridges and subduction trenches characteristic of Earth's plate tectonics even though the resolution of the Pioneer Venus altimetry was adequate to resolve them had they been present 17. If the tectonic features described above are assumed to be part of a smaller-scale plate tectonics system, it can be shown that such a system would be grossly inefficient in removing heat from the interior of Venus4,5,18.

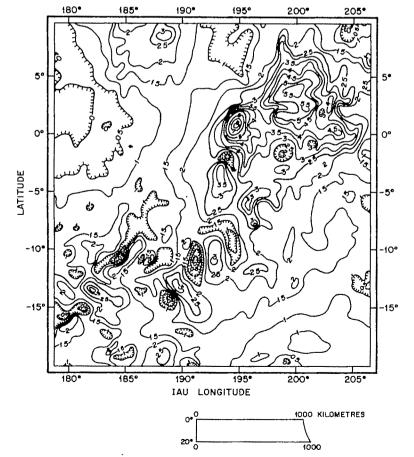

Surface properties and processes also provide some limited data bearing on the geological evolution of Venus. Igneous rocks on Venus are expected to contain minerals that are essentially identical with those found in common rocks on Earth (possibly excepting hydrous phases)12,13. These minerals should be chemically weathered by the venerean atmosphere. particularly at high elevations¹⁹. Aeolian transport of weathering products can result in atmosphere/rock chemical cycles because of the large variations in atmospheric pressure and temperature (\sim 60 bar and \sim 110K) that accompany the >13 km relief on Venus^{1,9}. Expected threshold friction speeds appear fully sufficient to erode and transport particulates given the $\sim 1~\text{m s}^{-1}$ free-stream wind velocities measured by Venera and Pioneer probes near the surface 12,13,20-22.

Earth-based and Pioneer radar determinations of the Fresnel reflection coefficient indicate that the surface of Venus cannot be covered by a thick (more than a few centimetres), areally extensive layer of porous regolith or aeolian sediment^{12,13}. It is possible, however, that

aeolian sediment is cemented by chemical reaction with the atmosphere, a process that would increase its bulk density and render it indistinguishable (to radar) from slightly weathered igneous rocks. Very high reflectivities that imply densities consistent with fresh mafic or ultramafic igneous rocks occur in only a few areas of high elevation, especially the southern part of Beta Regio²³. Presumably these areas are very young, or they are sites of active erosion.

Although both topographical data and thermal modelling predict that an Earthlike system of plate tectonics is not present on Venus now, the abundance of 40Ar in the atmosphere of Venus² suggests that the overall rate of tectonic and volcanic activity during its evolution has been only a little below that of Earth. Moreover, longwavelength gravity anomalies coincide in position with major topographical features, a correlation that, considering the hot lithosphere, suggests dynamic mantle support of the topography^{4,5,18}. How then is heat lost from the interior of Venus? Phillips (Lunar and Planetary Institute) suggests a tectonic style similar to intraplate, hot-spot tectonics on Earth^{4,5}. Perhaps Venus is characterized by a global system of domes, local rifts and active volcanic centres, with specific elements developing and decaying in concert with changes in the mantle flow patterns responsible for them, implying that little or none of the modern topography of Venus has survived from primordial times. This model suggests that modern Venus may well be tectonically similar to Archaean Earth.

Fig.3 'Pitted and hilly' terrain in eastern Aphrodite Terra. This terrain is much rougher to radar at both centimetre and metre scales than are the lower regions in the north-west and south-east corners of the map. Contour interval 0.5 km; datum is median radius.

Structure and energetics of the atmosphere

from F.W. Taylor

For many years now, the key question about the structure of the atmosphere of Venus, and the mechanisms that shape it. has been the origin of the high surface temperatures and pressures (over 750K and nearly 100 bar respectively). It is now reasonably certain that the atmospheric 'greenhouse effect', whereby incoming short-wavelength solar radiation penetrates the clouds more efficiently than outgoing long-wavelength thermal radiation, traps enough heat to account for the severe conditions in the lower atmosphere. The wealth of new data from the recent Pioneer Venus and Venera missions has placed calculations of the greenhouse model on a much firmer footing than previously, with measurements of the amount of solar heating at different altitudes, the vertical distribution of cloud opacity and the total IR flux escaping from the top of the atmosphere.

About 2.5 per cent of the energy from the Sun intersected by Venus reaches all the way to the surface. About 80 per cent is reflected back into space by the very reflective sulphuric acid clouds without being absorbed by the planet at all. Of the remainder, about half is absorbed above 60 km altitude (mostly near the very top of the clouds) and the rest below. It is somewhat disturbing that the best calculations of the thermal component of the 'greenhouse' still allow about 200 W m-2 to escape from the top of the atmosphere on average, whereas only 158 W m⁻² was observed by orbiting IR sensors. This suggests that there is a fairly important, but still unidentified, source of opacity in the clouds. However, the relatively low actual flux out makes it easier to 'balance' the greenhouse calculations at the required high surface temperatures. A further unresolved problem is that albedo (or reflectivity) measurements from the Earth and from space indicate that Venus keeps, on average, only about 145 W m⁻² of the flux from the Sun, raising questions about where the other 10 per cent or so comes from. The albedo is probably less than the present best value of 0.80 indicated by a preliminary analysis of the data, and it is being re-examined.

The most spectacular new features emerging from the recent rash of exploration lie in the atmosphere at the cloud tops and above. At these levels the radiative and dynamical time constants are less than the venusian day and interesting diurnal (daynight) and seasonal (equator-pole) structure has emerged, much of it poorly understood. At the highest levels, in the part of the atmosphere called the exosphere (Fig. 1), the temperature varies from 300K

F.W. Taylor is Acting Head of the Department of Atmospheric Physics, Oxford University, Clarendon Laboratory, Oxford OX1 3PU.

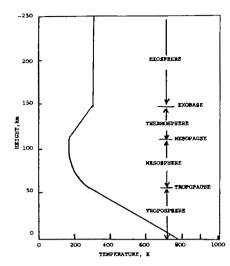

Fig.1 Nomenclature for the different atmospheric regions on Venus, based on the mean temperature structure by analogy with Earth. The thermosphere and exosphere are also known collectively as the 'upper' atmosphere, the mesosphere and troposphere as the 'middle' and 'lower' atmosphere respectively.

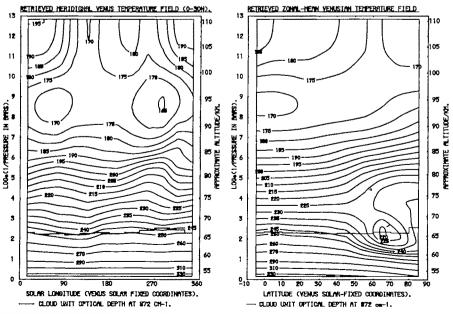

on the dayside (cooler than predicted by models) to a surprisingly low 100K on the nightside. It is very difficult to find cooling mechanisms efficient enough at these low pressures to explain the latter at all, and the very sharp drop which is observed across the terminator enhances the problem. At lower levels near the mesopause (Fig. 1), the temperature distribution is more nearly as expected, with 'warm' air (185K) near local noon, a 'cool' (170K) nightside and an

'intermediate' (175K) pole. However, the simple pattern is upset by a 'hot spot' of 185K near local midnight, where solar heating is a minimum. This is thought to be produced dynamically, perhaps by compressional heating in the descending branch of a symmetric sub-solar to antisolar circulation pattern. A little below the mesopause level, the distribution of temperature alters radically. At levels near 90 km altitude, the sub-solar point is the coolest on the planet and the poles are warmest. This remarkable state of affairs remains largely unexplained, although theories abound. These include absorption of solar radiation in a 'polar cap' of mesospheric haze, a 'hotplate' effect due to depression at the poles of the main cloud to warmer levels, and again dynamical heating, this time in the descending branch of a hemispherical Hadley-type cell. The reversed equator to pole temperature gradient persists nearly down to the cloud tops (Fig.2).

An interesting feature of any atmosphere is its response to the diurnal cycle of solar heating -- the thermal tides. Instead of the familiar wavenumber one fluctuation of the Earth's atmosphere (single maximum and minimum temperatures around an equatorial circumference), Venus surprises with a wavenumber two tide. Near the cloud tops, temperatures peak some 5K above the mean value in the morning and again in the second half of the night, with minima in the afternoon and post-duck quadrants. Why does Venus respond to predominantly wavenumber one solar forcing with a wavenumber two tide? Theorists are beginning to develop tidal models which are outlined below by Elson.

Even more obscure are the mechanisms which give rise to the two most pro-

Fig.2 (left) An equatorial cross-section through the mean atmospheric temperature field on Venus, from Pioneer Venus IR soundings. 0° solar longitude is the local noon, 90° the morning terminator and so on (remembering that Venus rotates in the retrograde sense). The stepped line near the bottom of the figure is the height of the main cloud top as a function of local time on Venus. Note the thermal tides. Fig.3 (right) As Fig.2, but an equator to pole cross-section (0° = equator, 90° = N pole). Note the polar warming and the circumpolar collar.

minent phenomena of Venus's atmosphere, the polar dipole and the circumpolar collar. The true nature of these was hidden from Earth-based observers for decades because they occur at such high latitudes (65–70° and 80–90° respectively) as to be foreshortened beyond recognition to all but the polar-orbiting Pioneer Venus Orbiter. They appear in PVO IR images as a very cold, nearly circular feature about 5,000 km in diameter centred on the pole (the collar) and two hot features, thought to be holes in the otherwise ubiquitous cloud cover, about 1,000 km either side of the pole and rotating around it (the dipole; see Nature 279, 613; 1979). A meridional cross-section of the temperature structure of the middle and upper atmospheres (Fig.3) reveals the collar as an intense, cold planetary-scale wave of long duration. It has been speculated that it is a disturbance produced at the boundary between the 'solid body' rotation of the atmosphere, which is observed in cloud-tracked winds and latitudes equatorwards of the collar, and the regime polewards in which the atmosphere accelerates in the zonal direction as it flows towards the pole, in an attempt to conserve angular momentum. This acceleration is evident in the high rotation rate (every 2.5 to 3 days) of the dipole at the centre of the collar. The dipole is the eve at the centre of the polar vortex on Venus, remarkable for its 'double' appearance. Two clearings in the polar cloud orbit around the pole, rather than the expected one at its centre. The dipole itself is perhaps the biggest mystery of Venus' atmosphere. and a prime target for future missions to

may reappear above 100 km and, as was discussed by Mayr, it seems to be required at altitudes above 150 km to explain Pioneer observations.

Atmospheric thermal tides, temperature and wind perturbations caused by solar heating of the atmosphere were addressed by several speakers. Elson discussed them from an observational and diagnostic point of view, suggesting that the temperatures observed by the Pioneer spacecraft are difficult to reconcile with our terrestrial experience, and that model calculations indicate that the tidal winds are probably small in amplitude and dominated by dissipative forces. Pechmann (California Institute of Technology) described theoretical calculations of tidal winds and temperatures using a model. Her results suggest that the tidal response of the atmosphere strongly depends on the mean (zonal and time averaged) zonal wind and static stability. A similar calculation of the tidal fields was made by Fels (Princeton University) but for a very different purpose. Assuming that the unusual observed warming at the poles has a nonradiative source, Fels chose to examine a dynamical forcing mechanism which relies on the interaction between tidally forced waves and the averaged flow whereby the tides force the averaged flow to descend in the polar regions. This descent produces warming at the pole due to adiabatic compression of the atmospheric gas as it moves down to higher pressures. To produce warmings as large as are observed, however, this mechanism must assume that the cloud level winds are much stronger than those observed.

Tides were not the only type of waves to be discussed during the session. Apt (Jet Propulsion Laboratory) reported the presence of waves with periods of 5.3 and 2.9 Earth days over the entire Northern Hemisphere between the cloud tops at about 65 km and 90 km. These waves are thermal perturbations observed at IR wavelengths. Del Genio (NASA Goddard Institute for Space Studies) reported the existence of a 5.2 day wave from UV observations. Perhaps there is a temperaturesensitive UV absorber present. In the area of theoretical wave calculations, a presentation was made concerning results produced by a general circulation model of the type used for comprehensive terrestrial studies. Young (NASA Ames Research Center) described calculations of baroclinically unstable waves whose terrestrial counterparts are responsible for most of what is called weather. As is the case on the Earth, these waves are caused in part by the vertical shear in the zonal wind. Despite this similarity, differences in the rotation rates and atmospheric structures of the two planets appear to produce different wave characteristics.

Dynamics of the atmosphere

from Lee S. Elson

ATTEMPTS to explain the observation that the entire atmosphere of Venus moves in the same retrograde (westward) direction provided one important focus of the conference. Schubert (University of California, Los Angeles, and see refs 1, 2) described the atmospheric circulation as it is now known from the Pioneer Venus and the Soviet Venera spacecraft. The atmosphere moves westwards at average speeds of up to about 110 m s⁻¹ and there is a meridional (north/south) cloud level cell analagous to the terrestrial Hadley cell. As shown in Fig.1 (from Schubert's paper). there is considerable variation in this flow with time. Therefore, the term '4 day wind' used to describe the periodicity of UV features advected by the retrograde winds is a misnomer, because the wind speed corresponds more closely to a 5 day period.

Several suggestions for the possible causal mechanisms of this flow were made in the context of comparative planetary meteorology. Mayr (Goddard Space Flight Center) and Williams (Princeton University) considered the role of meridional cells, viscosity and solar heating of the atmosphere in producing zonal (east/west) jets on Jupiter, Saturn and Venus. Their conclusions and the discussion with the audience indicated that one might expect such jets on Venus if several mechanisms operated simultaneously. However, model calculations are still unable to reproduce exactly the observed flow while simultaneously satisfying heat and momentum conservation constraints. Two papers dealing with the zonal jet above the clouds were also presented. Elson (Jet Propulsion

Lee S. Elson is a member of the technical staff of the Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91103.

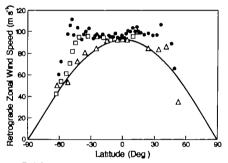

Fig. 1 Mean cloudtop westward wind as a function of latitude. Mariner 10 data from 1974 (filled dots) show different structure from that of Pioneer Venus as shown by the open symbols representing UV data presented by Del Genio.

Laboratory) described evidence³ that the zonal jet dies off with increasing altitude so that it has disappeared entirely above about 80 km altitude (see Fig.2). The jet

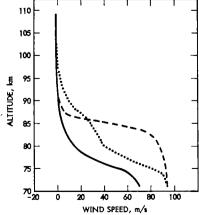

Fig. 2 Mean westward wind as a function of altitude above the cloud tops. The solid curve is the best estimate based on a model 4 and the other curves are the results of a study of the model sensitivity to input assumptions.

Clouds and hazes

from R.G. Knollenberg

THE Venus cloud and haze system summarized in Table 1 is planetary in nature with an enormous vertical extent of 50-60 km. The clouds are rather tenuous and were found to have an average visibility of about 1 km by early Venera nephelometer (particle backscatter photometer) measurements1. The main cloud deck is at an altitude of 45-70 km and includes particles of various compositions². Upper, middle and lower cloud regions are easily defined by transition layers and changes in size properties. Haze layers overlie and underlie the main cloud deck.

Through an analysis of polarimetry data, Kawabata has shown that the upper submicron aerosol haze has an average optical depth of about 1 in its most dense polar regions where it is a distinct layer above the main cloud deck3. In the equatorial and mid-latitude regions, it is about one-tenth as dense and is mixed with 2 μ m diameter monodispersed H2SO, cloud droplets at the top of the main cloud deck. The haze particles also have optical and physiochemical properties consistent with H,SO.

Ragent and Blamont's nephelometer data show a sharp base for the main cloud deck at 47-50 km at four different Pioneer Venus entry sites but thin filaments are also evident below the nominal cloud base4. Knollenberg and Hunten have shown that the size distribution is generally multimodal throughout the main cloud deck, which has an optical depth of 20-30 (ref.5). There are three size modes identified as mode 1 aerosol, which varies in composition with altitude; mode 2 H2SO4 droplets; and mode 3, which appears to include H2SO, droplets and perhaps crystals of unknown composition. Below the main cloud deck, small haze particles of low number density extend down to approximately 30 km, where all particles

Mode 1 is highly variable in all cloud regions and has been characterized as a background aerosol population with high number density but little optical depth except in the UV. Toon has shown that, in the upper cloud region, the mode 1 aerosols have a higher refractive index and seem to be rich in sulphur compounds⁶. In the lower cloud region, H2SO4 appears more plausible. Below the cloud deck, the mode 1 aerosols, which comprise the lower thin haze, appear to be desiccation products (cores) of cloud particle growth and decay.

The mode 2 H₂SO₄ droplets are probably several months old in the upper cloud region unless vertical exchange is faster than suspected, but perhaps only

Table 1 Summary of Venus cloud and haze properties

Region	Altıtude (km)	Temperature (K)	Optical depth T	Av. no. density (per cm ³)	Mean diameter (µm)	Composition
Upper haze	70- 9 0	225-190	0.2-1.0	500	0.4	H ₂ SO ₄
Upper cloud	56.5–70	286–225	6.0-8.0	(1)-1,500 (2)-50	Bimodal 0.4, 2.0	H ₂ SO ₄ + sulphur
Middle cloud	50.5-56.5	345–286	8.0–10	(1)-300 (2)-50 (3)-10	Trimodal 0.3, 2.5, 7.0	H ₂ SO ₄ + crystals (?)
Lower cloud	47.5–50.5	367-345	6.0–12	(1)-1,200 (2)-50 (3)-50	Trimodal 0.4, 2.0, 8.0	H ₂ SO ₄ + crystals (?)
Lower baze	31-47.5	482–367	0.1-0.2	2-20	0.2	H ₂ SO ₄ + acrosol
Pre-cloud layers	46, 47.5	378, 367	0.05, 0.1	50, 150	Bimodal 0.3, 2.0	H ₂ SO ₄ + aerosol

hours old in the lower cloud region. At upper altitudes, H2SO4 droplets are likely to be contaminated after scavenging aerosol over their long lifetime. Near cloud top, H₂SO₄ vapour should be sufficiently supersaturated to support a bimodal population; that is, small droplets can nucleate and grow even in the presence of an existing larger droplet population. The mode 2 H2SO4 droplets nucleate and grow in the upper cloud region. Knollenberg and Hunten observe a gradual increase in number density descending through the main cloud deck. The mode regenerates through condensation in the lower layers. Its size distribution is exceedingly narrow at any one altitude — growth models of Turco and Toon indicate that dominant but competitive droplet diffusional growth can explain this⁷. The mode 2 distribution is uniform over most of the planet and is indicative of its extreme stability.

Analysis of particle image data by Knollenberg and Hunten showed the largest mode 3 particles to be asymmetric and suggested a crystalline species interpretation. Toon has shown that the radiative flux and single particle optical data are consistent without a crystalline species⁸ and favours H₂SO₄ droplets. Additional measurements will probably be required to resolve this controversy.

The entire Venus cloud system has an optical depth of 20-35 at visible wavelengths. Taylor reports a radiometric albedo of 0.77-0.82, increasing from equator to pole9. His IR radiometer data have revealed a strong dipole circulation near the poles. Tomasko finds single scattering albedoes ranging from a low of 0.995 in the upper cloud region to 0.999 in the lower cloud region¹⁰. For most of the radiometric spectrum the planet appears featureless; however, fascinating contrasts are observed in the UV via partially understood absorption processes. Pollack and Esposito find that sulphur dioxide is responsible for absorption at short UV wavelengths, but the identity of the absorber visible from Earth in the near-UV

remains unknown^{11,12}. Particulate sulphur (mode 1) appears to be a possible choice for secondary absorber. The related question of how the physical and/or chemical processes at the cloud top act to bring about the horizontal variability of these absorbing constituents is still a puzzle.

The main cloud deck is embedded in the zonal circulation at altitudes of greatest wind velocity and vertical wind shear. The clouds are all of stratiform morphology. Cloud particle growth is not strongly influenced by either the large-scale circulation or the latent heat released during condensation. The clouds are most strongly influenced by radiative exchanges. Because of the temperature extremes, there is a rather large scale of H₂SO₄ droplet growth times ranging from months in the upper hazes to hours in the lower cloud region. There is little evidence for the existence of large precipitation particles. Known processes for the formation of the lightning observed by Ksanformaliti and Scarf^{13,14} require both. If cloud processes generate the lightning, then much larger undetected particles must exist. Scarf has suggested that the Venus lightning is phaselocked with the surface and may be solely the result of volcanic activity 15.

essentially disappear.

Structure and dynamics of the ionosphere

from A.F. Nagy and L.H. Brace

A general view of the ionospheric structure of Venus and of the major processes operating there are shown in the figure. Solar extreme ultraviolet (EUV) radiation falling on the thermosphere creates the daytime ionosphere, which is in photochemical equilibrium near its peak at about 142 km, where the major ion is O2+; transport processes become dominant above about 200 km, where the major ion is O⁺. The upper ionosphere is in near diffusive equilibrium much of the time, although ion transport to the nightside and the loss of plasma through the ionopause frequently cause departures from diffusive equilibrium at high altitudes and in the region near the terminator. A comparison of calculated and measured ion composition indicates that we have achieved a first-order understanding of the very complex photochemical processes involved. Recent suggestions for the inclusion of a large number of specific reactions involving metastable species have even further narrowed the differences between the models and the experimental results. The dayside ionosphere is heated internally by solar EUV-generated photoelectrons and heated from above by the downward conduction of solar wind energy deposited at the ionopause. The ion gas also receives heat from exothermic chemical reactions

A.F. Nagy is Professor of Atmospheric Science at the Space Physics Research Laboratory, University of Michigan, Ann Arbor, Michigan 48109, and L.H. Brace is at the NASA Goddard Space Flight Center, Greenbelt, Maryland and Joule or frictional heating.

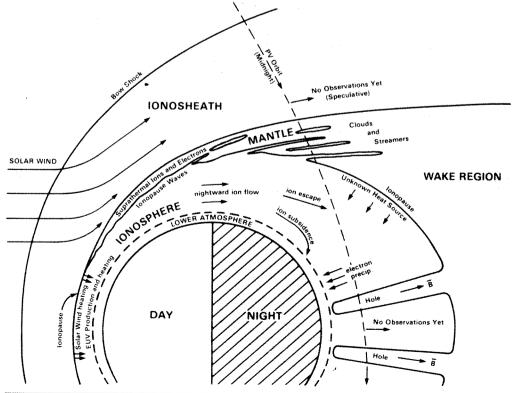

The day-to-night plasma pressure gradient across the terminator drives a nightward flow of ions, usually at supersonic velocities; some of these ions subside to contribute to the formation of the nightside ionosphere. The great variability of the nightside ionosphere is believed to arise from changes in the proportion of the flow which is lost to the wake. Even without the nightward ion flow, a nightside ionosphere would be formed by the precipitation of electrons with energies up to a few hundred electron volts, although the measured electron fluxes do not appear adequate to be the only source of the observed nightside ionization.

Large-scale radial holes or plasma depletions extend downwards to nearly the peak of ionization in the antisolar region. These holes, which occur in north-south pairs, enclose regions of strong radial magnetic fields that are believed to originate in the magnetotail of Venus. The holes or, more precisely, the radial magnetic fields act as a barrier to the flow of ionization into the antisolar region and may be related to the greatly elevated ion temperatures observed there. It has been suggested that the holes are formed by the removal of plasma by outward acceleration caused by magnetotail-generated electric fields.

The ionopause itself is a highly dynamic and complex surface which extends from an average altitude of 290 km at the subsolar point to about 1,000 km at the terminator. Its altitude varies from 200 to

more than 3,000 km on the nightside. though its height in the antisolar region will not be measured until further increases occur in the Venus orbiter periapsis altitude during the next few years. The increase in ionopause altitude from the subsolar point towards the terminator reflects the decrease of solar wind dynamic pressure with solar zenith angle. The ionopause altitude is highly variable, with a time constant of probably less than one hour. On the dayside, a near static balance between the solar wind and ionospheric plasma pressures is maintained, which results in an ionopause altitude variation which is inversely proportional to the wind pressure. The solar wind pressure is conveyed to the dayside ionosphere primarily by means of an enhanced magnetic field approximately parallel to the ionopause surface, although some of the solar wind plasma may interact directly with the ionospheric plasma.

Just above the ionopause is the mantle, a transition region between the ionospheric plasma and the flowing shocked solar wind plasma. A variety of solar wind interaction products are observed in the mantle, including suprathermal ions and electrons, ionospheric photoelectrons, enhanced plasma wave activity, and clouds or streamers of ionospheric plasma that appear to be swept downstream by ionosheath flow. These features are probably signatures of the plasma processes that form the ionopause and divert the solar wind about Venus; however the specific processes have not yet been identified.

Current views of the ionospheric structure of Venus, showing the major processes that are believed to be operating in the region. The scale of the ionosphere is increased by a factor of three relative to the ionosheath for clarity of presentation (reproduced from Brace, L.H. et al. The Ionosphere of Venus: Observations and their Interpretation, Venus, University of Arizona Press; 1982).

The solar wind interaction

from P.A. Cloutier and C.T. Russell

VENUS provides our only well documented example of the interaction of supersonic or, more correctly, supermagnetosonic magnetized plasma with an unmagnetized and highly-electrically conducting ionosphere. The Pioneer Venus observations confirm the zero-order picture derived from the earlier Venera and Mariner missions as sketched in Fig.1. A bow shock forms in front of the planet which heats, slows and deflects the flow around the ionosphere. The magnetic field is draped over the obstacle and increases in strength towards the planet while at the same time slipping around the planet as the plasma flows out of the plane of the figure. The physics by which this behaviour takes place is fairly well understood. The interesting physics, and that unique to Venus, at least so far, involves perturbations of this picture. These perturbations provided much of the controversy in the discussions of the solar wind interaction on the last day of the Venus conference.

Venus has a magnetic tail very like a comet. The Pioneer Venus magnetometer shows that behind Venus, in a region about 4 Venus radii across, the magnetic field is parallel to the solar wind flow and enhanced above interplanetary levels. Barnes (NASA Ames Research Center) and Intriligator (Carmel Research Center) reported that in the distant tail, interesting plasma effects are seen, including regions of depletion of solar wind plasma and regions of pick-up of ionospheric oxygen ions. Closer to the planet, Barnes observed the acceleration region for the oxygen pickup. Near the terminator, the oxygen flow was weakest and fastest at high altitudes, growing in density and decreasing in speed as the planet was approached.

The source of this oxygen is presumably charge exchange and photoionization of the hot neutral oxygen exosphere at altitudes above the normal ionosphere. At high altitudes, this new cold plasma is accelerated either by the solar wind electric field or by magnetic stresses and escapes from the planet. At low altitudes, in the ionosphere, the magnetic and electric fields are weak and new ions remain bound by the planet's gravitational field. It is difficult to assess how important these processes are. Vaisberg and Zeleny (Space Research Institute. Moscow) have modelled mass loading of field lines due to photoionization in a cylindrical geometry but find that the flux of oxygen is too low. Perhaps charge exchange will provide the

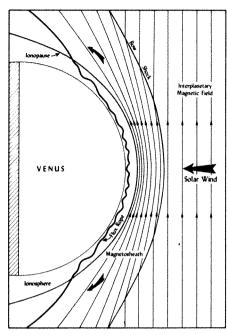

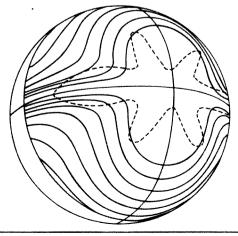

Fig. 1 Sketch of the interaction of the magnetized solar wind plasma with Venus's unmagnetized and highly-electrically conducting ionosphere.

missing flux but they prefer a source of anomalous ionization. Another indicator of the importance of these non-magneto-hydrodynamic processes is the position (Slavin, UCLA, and Mihalov, NASA Ames Research Center) of bowshock. The shock is somewhat weaker and closer to Venus than would be expected if all the solar wind were deflected by the planet. Charge exchange could provide the requisite removal of momentum from the flow.

Fig. 2 Magnetic field line configuration on Venus's dayside (see the text). The dashed line shows the boundary separating regions stable and unstable to the Kelvin-Helmholtz instability.

Some of these phenomena were anticipated by a minority of scientists before the latest barrage of data from Pioneer Venus. Many, however, were not. Two unexpected phenomena were discussed by Brace (NASA Goddard Space Flight Center): plasma clouds, dense regions of cold plasma apparently detached from the ionosphere proper in the terminator region and ionospheric holes, regions of density depletion accompanied by radial magnetic field in the near midnight ionosphere. Another unexpected feature of the dayside ionosphere is the existence of magnetic flux ropes, twisted bundles of magnetic flux which often pervade the dayside ionosphere. An artist's conception of the occurrence of such a rope is given in Fig.1.

Flux ropes and other observed features of the dayside ionospheric configuration may be explained as resulting from induced convection within the ionosphere driven by the solar wind interaction. In a model proposed by Cloutier (Rice University) and his colleagues, pressure gradients and electric fields induced in the ionosphere drive an anti-sunward convection pattern which carries ionization and the draped interplanetary magnetic field towards the anti-solar point. In the model, velocity shear within the ionospheric convection pattern leads to flux rope formation due to the onset of the Kelvin-Helmholtz instability. Calculations of the ion convection patterns, the field geometry and the extent of the Kelvin-Helmholtz unstable regions reproduce many of the observed characteristics of the dayside Venus magnetic field behaviour, including the presence or absence of flux ropes, the occurrence of large magnetic fields at low altitudes, and the lack of coincidence of times between the ionopause and large magnetic gradients. The field line configuration is shown in Fig.2 by the solid lines, and the dashed contour shows the boundary between region stable and unstable to the Kelvin-Helmholtz instability. Flux rope formation may occur outside of the dashed contour.

The importance of the Kelvin-Helmholtz waves at the ionopause was discussed by Curtis (NASA Goddard Space Flight Center) who described the acceleration of ionosheath plasma by parallel electric fields arising from conversion of Kelvin-Helmholtz wave energy into a kinetic Alfvén wave. Curtis also showed that ions and electrons may be thermalized to high energies by high levels of plasma wave turbulence at Venus.

Finally, there are still some classical interaction problems to be solved: how, for example, does the flow close behind Venus (Knudsen, Lockheed), and is the interaction viscous rather than inviscid as preferred by Knudsen (Pérez-de-Tejada, Institute Geofisica, Mexico). In all there was a great deal of controversy and evidence of many more important principles to be uncovered in the solar wind-Venus interaction problem.

Resolution of conglomerates by stereoselective habit modifications

L. Addadi, Z. Berkovitch-Yellin, N. Domb, E. Gati, M. Lahav & L. Leiserowitz

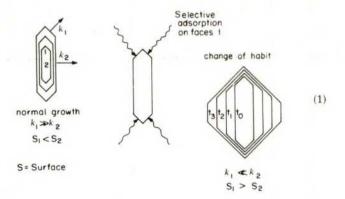

Department of Structural Chemistry, The Weizmann Institute of Science, Rehovot 76100, Israel

A method for resolution of conglomerates, based on morphological differences between the enantiomorphic crystals induced by tailor-made resolved impurities is described. The relationship between the crystal structure of the affected enantiomorph and the stereochemistry of the added impurity is analysed in the systems glutamic acid. HCl, asparagine. H_2O and threonine in the presence of L- or D-amino acids, and it is found that the additive binds stereoselectively at the surface of the enantiomer of the same absolute configuration, occupying the same site of the amino acid groups of the host molecule. The modified side chains perturb in a second stage the regular growth of the crystal in the directions along which the side chains of the host are hydrogen bonded.

IN 1848 Louis Pasteur found that racemic sodium ammonium tartrate crystallizes as two monohydrates of enantiomorphous habits¹. His separation of these two types of crystals and the observation that in solution they showed optical rotations identical to those of solutions of the separate enantiomers established the foundations of modern stereochemistry.

This crystallization behaviour might have escaped Pasteur's attention had not the enantiomeric crystals in this system been readily distinguishable visually: the 'laevo' and 'dextro' crystals have particular 'hemihedral' faces, which make the habits enantiomorphous². This experiment is remarkable because the combination of such 'spontaneous resolution' with visual distinguishability ('hemihedrism') is rare³, with less than a dozen examples having been recorded⁴.

Our recent discovery of a new and general method for kinetic resolution of conglomerates also allows the assignment of absolute configuration of chiral molecules^{5,6}. In connection with a study on generation and amplification of optical activity in prebiotic conditions^{7–9}, we found that the crystallization of a conglomerate $\{R\}+\{S\}$ is influenced in a dramatic way by the presence of small amounts of a resolved impurity S'. Selective adsorption of the additive S' on the growing $\{S\}$ crystals, of similar stereochemistry, induces a substantial decrease in growth rate of these crystals, allowing their kinetic separation from the unaffected $\{R\}$ crystals. This same effect causes the $\{S\}$ crystals to undergo, during growth, morphological changes which can be extreme ^{10–14} and which allow easy visual identification and separation of the two enantiomorphs scheme (1).

This phenomenon offers the possibility of modifying the classical Pasteur experiment and of extending it to systems which undergo spontaneous resolution but do not display hemihedrism³.

We describe here the morphological aspects of this selective adsorption process and discuss how they affect the action

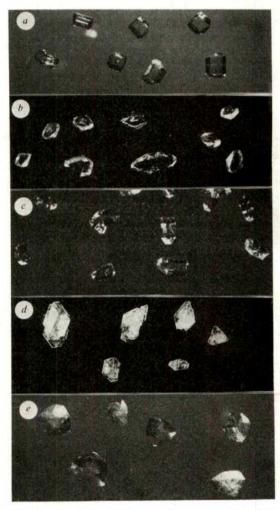

Fig. 1 Crystals of Asn. H_2O grown in presence of additives: a, none, or D-Asn + (L) additive; b, L-Asn + L-Gln; c, L-Asn + L-Ser; d, L-Asn + L-Asp; e, L-Asn + L-Orn. In each case the crystals were obtained from D, L-Asn as a mixture of D-Asn displaying a morphology as in a, and L-Asn as in b, c, d or e, depending on the impurity.

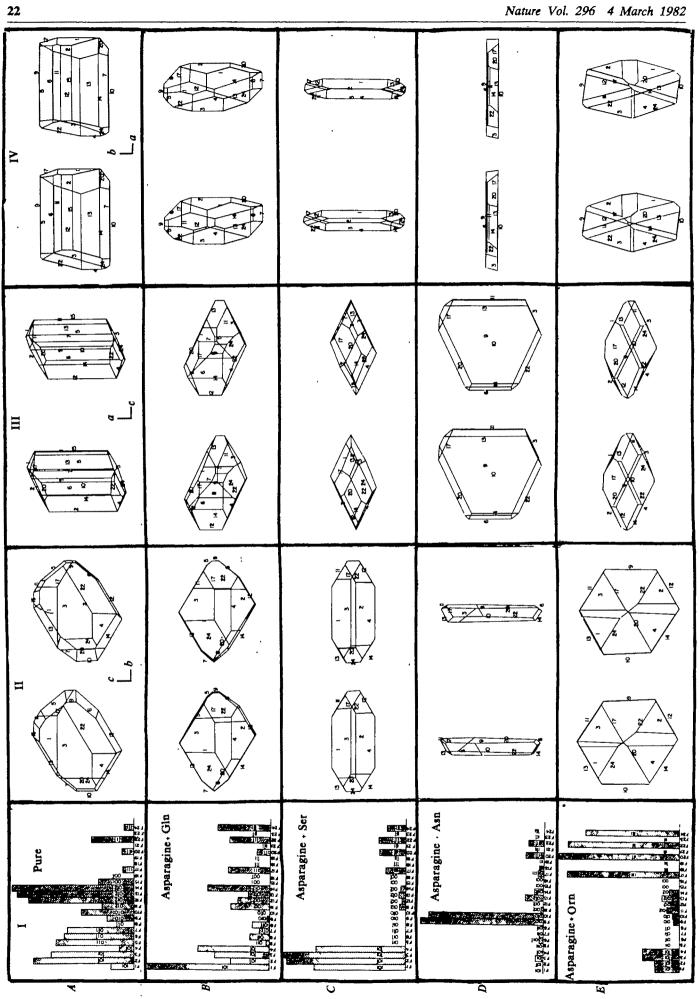

Fig. 2 A comparison between crystals of L-Asn. H₂O grown in presence of various additives: A, none; B, L-Asn+L-Gln; C, L-Asn+L-Ser; D, L-Asn+L-Asp; E, L-Asn+L-Orn. The hkl Miller indices of these faces are shown on the histogram. (II), (III) and (IV) are computer-drawn stereographic pictures of the crystals viewed, respectively, along axes a, b and c, which form a right-handed system.

mechanism of the additive. We shall examine the stereochemical relationship between the additive and the crystal structure of the substrate, in order to exploit this knowledge for controlling crystal morphology. The conglomerates of D, L asparagine monohydrate, [D, L-Asn . H_2O] D, L-threonine [D, L-Thr] and D, L-glutamic acid hydrochloride [D, L-Glu . HCl] were selected for study.

Results

D, L-Asn crystallizes from neutral aqueous solutions in the form of a conglomerate [D+L] Asn. H₂O of space group P2₁2₁2₁ (refs 15-17). The crystals show a prismatic morphology with 18 well-developed faces (Figs 1a, 2A). We have found that resolved glutamic acid (Glu), aspartic acid (Asp), glutamine (Gln), serine (Ser), lysine (Lys), ornithine (Orn) and histidine (His) are effective in the kinetic resolution of racemic Asn; these same impurities were selected for morphological studies. Various batches of 100% supersaturated solutions (300 mg per 3 cm³) of D, L-Asn in water were prepared by cooling to room temperature hot filtered solutions, to which resolved impurity (L or D, 5-50 mg) had been added. Crystallization could be accomplished either spontaneously on standing for 1 or 2 days or on seeding with a powder of D, L crystals. In all cases crystals with a normal morphology precipitate first, but after a while (hours or days depending on the efficiency and concentration of the impurity) there appear crystals of distinctly different habit. The precipitates are then separated by decantation, dried and examined (Fig. 1). The crystals of changed and unchanged morphologies have identical internal structure, as checked by both powder and single crystal Weissenberg diffraction photographs, but consist of only L and D enantiomers, respectively, when L impurity is used (and vice versa when D impurity is used) (some typical results are reported in Table 1).

A decrease in concentration of the impurity (from 50 to 5 mg per 3 cm³) results in a progressive decrease in the modification of the affected enantiomer's morphology.

HPLC measurements, carried out in conditions in which Dand L-amino acids are resolved^{18,19}, confirmed that in the crystallization of pure L-Asn in the presence of racemic impurity (D', L'), L' is absorbed preferentially by the L crystals. Molar ratios of L'/D' from 6:1 for D, L-Glu to 30:1 for D, L-Asp were found²⁰.

To check the distribution of the D' and L' impurities in the L crystal grown in this way, single crystals (3–5 mg) were subjected to progressive dissolution in pure water, and the various fractions were analysed by HPLC. While the D' impurity was found only in the first dissolution fractions from L-Asn crystals, L' impurity was present in all fractions at approximately constant concentration. These results strongly support the idea that the impurity is situated only at the outer surface of the substrate crystals of opposite chirality, whereas it is occluded throughout the bulk of the crystal of the same chirality. Clearly the stereochemical similarity between L and L' is the key to the resolution process and to the morphological changes.

To try to clarify the mechanism of the adsorption process, we measured the dimensions, including the areas of all faces, of affected and unaffected crystals, and thus established which growth directions and the areas of which faces are modified by the occlusion of the impurity scheme (1). The crystal dimensions were determined on a diffractometer by measuring the perpendicular distance of each face from a convenient reference point²¹. These measurements were used to derive the coordinates of the bounding corners of the crystal from which the areas of the faces were calculated and the stereographic pictures of the crystals drawn.

Table 1 Morphological separation of enantiomers of D, L-Asn crystallized in the presence of additives*

Additive		Absolute		Enantiomeric
(mg)	Morphology	configuration	$[\alpha]_{\mathbf{D}}$	purity (%)†

^{*} From aqueous solutions of concentration 300 mg per 3 cm³.

Figure 2 presents histograms of the measured areas for all the faces of typical crystals of pure L-Asn, L-Asn+L-Gln, L-Asn+L-Ser, L-Asn+L-Asp, and L-Asn+L-Orn, together with computer-drawn stereoscopic pictures of the crystals. Comparison of the histograms shows that, for the impurities L-Ser and L-Gln (Fig. 2B, C), the faces whose areas are relatively enhanced are {101} and, to a smaller extent, {111}, whereas the {011} and {012} faces are reduced in size. L-Glu, L-Orn, L-Lys and L-His induce similar morphological changes but, for the last three (Fig. 2E), the {111} faces are more developed than {101}. L-Asp, in contradistinction, causes L-Asn crystals to assume a completely different platelet-like morphology with predominant faces {010} (see Fig. 2D).

The influence of impurities on the two substrates (2a) and (2b) are described below.

D, L-Glu. HCl crystallizes in space group P2₁2₁2₁ (refs 22, 23) exhibiting a morphology depicted in scheme (2a). Crystallization experiments were performed by dissolving 1 g D, L-Glu. H₂O in 5M HCl (5 cm³) together with variable amounts of resolved L' impurity, filtering the hot solutions and cooling to room temperature (100% supersaturation).

Addition of small amounts (0.5 mg) of seed crystals of racemic Glu. HCl to the cooled supersaturated solution resulted in the initial separation of big crystals of D-Glu. HCl with a morphology as in Fig. 3a. In a second stage (after hours or days depending on the efficiency and concentration of the impurity)

[†] Samples ranging from 70 to 80 mg in weight.

there appeared crystalline powder composed of the L-enantiomer (Fig. 3f). On the basis of resolution power and morphological change the effective impurities may be divided into two groups, one consisting of the basic amino acids L-Lys . HCl, L-Orn . HCl and L-His . HCl, and the other of L-Cys . HCl, L-Thr and L-Ser. The former group, when used in high concentration (above 200 mg per 5 cm3 for His, 100 mg per 5 cm3 for Lys and Orn), strongly depresses the growth of L-Glu. HCl crystals which, however, eventually separate out in powder form (Fig. 3e). When Orn, Lys and His are added in concentrations as low as 10-25 mg per 15 cm3, morphological resolutions can still be performed successfully, the L enantiomer crystallizing in the form of thin $\{001\}$ platelets (Fig. 3b-d). The second group of impurities, Cys. HCl, Thr, Ser, are effective to a lesser extent: the maximal morphological change consists only of a decrease of the thickness of the {001} crystal plates. HPLC experiments, performed as for Asn, showed preferential adsorption on L-Glu . HCl of L' impurity which again proved to be present throughout the bulk of the crystal at a uniform concentration (0.5), while D' is present only in the surface layers of the crystal.

D, L-Thr also crystallizes in space group P2₁2₁2₁ (ref. 24) with a morphology as shown in scheme (2b). The most effective tested impurities in the case of Thr are resolved Glu, Asp, Asn and Gln. The crystals obtained from 100% supersaturated filtered solutions (900 mg D, L-Thr in 5 cm3 pure water), in the presence of these impurities, appear in the form of bars coated with powder (Fig. 3b). As the crystals twin easily, morphological studies were best performed by separate crystallization of L-Thr in the presence of L' and D' impurities, performed in parallel in identical conditions. Photographs of crystals of pure L-Thr (Fig. 3g) and of L-Thr crystallized in the presence of increasing amounts of L-Glu (Fig. 3h-j) show gradual morphological modification. On the other hand the morphology of L-Thr is left unchanged by the presence of the same amounts of D-Glu. The impurities mainly affect the growth of the {210} faces of the bar-like crystals, turning these crystals first into thin needles and eventually into powder.

Discussion

Having characterized the morphological changes in terms of specific directions of crystal growth we shall now investigate whether we can obtain information about the situation of the occluded molecule in the substrate lattice, and the associated question of the correlation of the stereochemistry of the impurity molecule with its morphological influence.

We note that well-developed faces arise from strong attractive forces between molecules forming a layer parallel to the face. The tendency for growth in a certain direction depends on the attachment energy between the layer of molecules on the crystal face and the rest of the crystal²⁵. The habit changes indicate that introduction of the impurity perturbs the layer and the attachment energies for the various faces to different extents.

In all three systems $\operatorname{Asn.H_2O}$, $\operatorname{Glu.HCl}$ and Thr , the effective impurity molecules have an arrangement of the carboxyl and amino groups directly attached to the asymmetric carbon identical to that of the host, but with different side chains. In crystals of all three substrates (Figs 4–6) the amino and carboxyl groups attached to the asymmetric carbon atom participate in several H-bonds. We expect that, in the 'doped' crystals, the H-bonding groups of the occluded impurities will occupy the same positions as do the corresponding groups of their host substrates, as they supply equivalent strong interactions. Thus the side chains of the impurities replace those of the substrates, but introduce contacts which differ from those of the host molecule. We shall account for the changes in crystal habit in terms of the effects of the contacts made by the impurity side chain at various crystal faces.

In the crystal structure L-Glu . HCl each side chain is directed approximately along the c-axis and makes H-bonds in this direction (Fig. 4). Thus it is clear why impurities such as L-Lys . HCl, L-Orn . HCl, L-His . HCl, L-Thr and L-Ser inhibit growth along the c-direction, decreasing the thickness of the $\{001\}$ plates of the crystal.

We first examine the striking morphological modification brought about by L-Asp on L-Asn, where the essential structural change at the site of the impurity is the removal of one H-bonding amide H atom of Asn. Contrary to other additives, which are found in the bulk of the substrate crystal in amounts ranging from 0.5 to 1%, up to 12% of L-Asp has been found in single crystals of L-Asn, indicating formation of solid solution between additive and host. We therefore measured the cell dimensions of several pure and affected L-Asn crystals (four of each). The average cell dimensions of pure L-Asn are a =5.582(2), b = 9.813(3), c = 11.791(4)Å, those of L-Asn + 10% L-Asp are a = 5.567(3), b = 9.835(5), c = 11.785(3)Å. These axial changes are compatible with the occluded Asp having its carboxy group in a cis rather than trans configuration. (There is much literature evidence in favour of the cis O-H bond. The trans O-H bond has not been found, with one exception²⁶, when O-H participates in an intramolecular O-H···O bond²⁷.) The shortening along a of 0.015 Å is in keeping with replacement of the N-H(cis)---O bond, of length 2.94 Å and directed with a

A

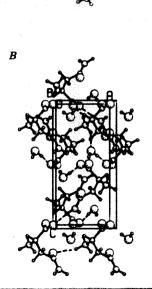

Fig. 4 Stereographic packing diagrams for L-glutamic acid. HCl as viewed along the a-axis.

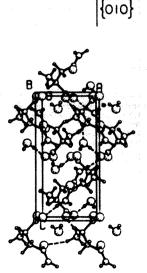

large component along a (Fig. 5), by an OH(cis)···O bond which tends to be 2.6 Å in length. The increased length of the b axis of 0.022 Å is in keeping with a replacement of the N-H(trans)···O bond, of length 3.05 Å and directed mainly along b (Fig. 5A), by an O···O contact which may be as long as 3.5 Å; this O···O interaction is repulsive because the lone pair electrons of these two atoms are directed towards each other²⁶⁻²⁹. Indeed these two new interactions introduced by the impurity, namely the attractive O-H···O and the repulsive O···O ones, may explain the formation of $\{010\}$ plates of the affected crystal. The $\{010\}$ layer energy is enhanced by the former, while the $\{010\}$ attach-

ment energy is severely reduced by the repulsive O···O interaction, thus developing large {010} faces.

The impurities L-Gln, L-Glu, L-Orn, L-Lys, L-His and L-Ser on L-Asn all have the same general effect: the preferred crystal growth along the a direction is replaced by a tendency for growth along b, and concomitantly with a reduction in area of the $\{011\}$ faces. We may rationalize these morphological changes as follows. First, the amide N-H(cis).--O (carboxy) and amino N-H---O (amide) bonds, which are directed mainly along the a-axis (see Fig. 5B) would be absent at the site of impurity, thus inhibiting growth along a. Furthermore the Asn molecules

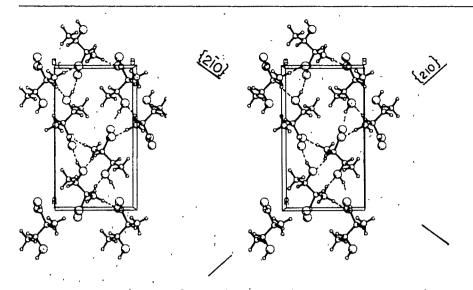

Fig. 6 Stereographic packing diagram for L-threonine as seen along the c-axis. The directions parallel to the affected faces are indicated.

related by the a translation form the highest number of contacts per pair of molecules, and thus growth along this direction should be the most affected. The relative increase of growth along b for affected crystals may be appreciated when we note that only one amide N-H--O bond directed almost along b would be absent at the site of the impurity.

The rupture of the OH---O bond of the side chain hydroxyl of the substrate Thr at the site of the impurity would certainly inhibit growth of the {210} faces perpendicular to the needle c-axis, as the O-H---O bonds are directed almost parallel or perpendicular to these faces, thus lowering both their layer and attachment energies (Fig. 6). However, the growth along the needle c-axis should not be dampened. Thus the observed effect of impurities, including thinner needles and eventually powder, is compatible with such a model.

Conclusions

On the basis of all our data, we suggest a mechanism involving two steps:

(1) Binding: the strong interactions between the amino acid group NH₃+-CHCOO of the substrate and the molecules at the growing site lead to binding of the impurity molecule at the surface of the crystal, in the same way as a substrate molecule is bound. A high degree of stereospecificity is needed to fit the chiral additive to the structured surface, and this explains the L'/D' selectivity of the effect.

(2) Inhibition: once the impurity has been adsorbed at the surface, it disturbs the regular deposition of the next layer of substrate molecules in the specific direction along which the modified side chain group emerges. The obstacle is eventually removed by overgrowth resulting in the inclusion of the foreign material in the bulk of the crystal. This mechanism would rationalize the different inhibition power of the various impurities, in terms of the hydrogen bonding and acid-base properties of the side chains of these molecules (for example, the strong effect of L-Lys, L-His and L-Orn on L-Glu. HCl).

It is instructive to consider the implication of this mechanism for crystals containing a polar b axis. Here the faces (hkl) and $(h\bar{k}l)$ have different structures³⁰⁻³³. Thus their growths can be affected differentially by an appropriate 'tailor-made' impurity. The specific morphological changes induced would then allow us to determine the absolute configuration of the substrate akin to the Bijvoet method. Studies in these directions on the systems L-Lys. HCl, and (L) cinnamoyl alanine, have been successful and are reported in the following paper³⁴

Finally, apart from providing us with a method for controlled modification of crystal morphology, this work allows a deeper - understanding of the role of the tailor-made impurity thus strengthening the empirical approach for assignment of relative configuration we proposed previously¹⁰, it also enables us to select better additives for efficient kinetic large scale resolution of conglomerates, and for growing single crystals of interest for material science and crystallographic measurements.

Parallel calculations of intermolecular interactions presently in progress, using existing techniques35, have already provided a quantitative basis for the mechanism proposed above, for simple systems such as benzamide-benzoic acid (Z.B.-Y., L.A., M. Idelson, M.L. and L.L. work in preparation).

We thank the Volkswagen Stiftung and the US/Israel Binational Fund for financial support, and Professor M. D. Cohen for critical reading of the manuscript.

Absolute configuration of chiral polar crystals

Z. Berkovitch-Yellin, L. Addadi, M. Idelson, L. Leiserowitz & M. Lahav

Department of Structural Chemistry, The Weizmann Institute of Science, Rehovot 76100, Israel

A method is described for direct determination of absolute configuration of chiral polar crystals, based on changes in crystal habit induced by tailor-made impurities. The method embodies the assignment of the direction of the chiral substrate molecule with respect to the crystal polar axis based on differences in the hemihedral faces of the substrate crystals as grown from solution in the presence and absence of impurities. The molecular packing requirements and the choice of impurities for application of this method in lysine and trans-cinnamoyl alanine are outlined.

THE configuration of chiral molecules had been defined only relatively, until 1951 when Bijvoet applied the method of anomalous dispersion of X rays to crystals of ammonium rubidium tartrate, thus placing stereochemistry on an absolute scale¹. In 1973 it was shown that two other, independent methods, noble gas ion reflection mass-spectrometry² and circular dichroism³⁻⁵, give chirality assignments which are in accord with the assignments according to Bijvoet (see review in ref. 6).

The assignment of the absolute configuration of chiral molecules in chiral crystals which develop hemihedral faces has long challenged the chemical crystallographer. In principle any method which establishes the orientation of a given functional group of the molecule with respect to the crystal axes or to a hemihedral face bounding the crystal, fixes the absolute configuration of the molecule. Several attempts have been made to deduce absolute configuration from crystal habit. Waser⁷ tried to establish the absolute configuration of D-tartaric acid by correlating the relative rates of growth of the hemihedral (hkl) and (hkl) crystal faces with the ease of attachment of the 'free' molecule at either face. However, Bijvoet⁶ later showed Waser's conclusions to be incorrect. Indeed, Turner and Lonsdale⁸ had earlier criticized Waser's reasoning, arguing that, within the limits of his assumptions, the ease of approach at either face is identical. In 1949 Wells examined the differences in the habit and growth directions of the polar crystals of resorcinol grown from various solvents. He interpreted the solvent effects as being due to the different interactions of the solvent with the different exposed faces of the crystal, which have polar OH groups at one end and hydrophobic benzene groups on the other. Booth and Bukley10 proposed that the same kind of interactions may be responsible for the growth behaviour of ethylenediamine tartrate (monohydrate) crystals, pure or in the presence of boric acid. Paul, Curtin and co-workers^{11,12} recently correlated the direction of the unique polar axis of p-bromobenzoic acid anhydride crystal with that of the preferential attack of ammonia gas on appropriate faces of single crystals of this compound.

Our recent studies on morphological changes in organic crystals as induced by 'tailor-made' impurities¹³ suggested a new direct method for the assignment of absolute configuration of chiral crystals and molecules. This method embodies the establishment of the orientation of the chiral molecule with respect to the crystal polar axes.

Crystal morphology change and nature of added impurity

Kinetic resolution of a large variety of racemic conglomerates in the presence of tailor-made impurities revealed, in many systems, stereoselective adsorption of the impurity at the surface of one enantiomorph, followed by drastic changes in its crystal habit, while the other enantiomorph remains unchanged¹⁴. Through these habit changes, a stereochemical correlation has been established between the molecular structure of the

impurity, the crystal structure of the substrate, and the affected growth directions.

A detailed study of such morphological changes induced in the crystals of L-asparagine. H₂O, L-threonine and L-glutamic acid.HCl, by other L-amino acids used as additives, led to the proposal of a two-step mechanism of binding and inhibition¹³. By virtue of strong attractive interactions (H-bonds, ionic) the unmodified (with respect to substrate molecules) amino acid group of the impurity binds stereospecifically at a site suited to the amino acid group of the substrate molecule on the surface of the host crystal. However, the modified chain of the occluded impurity perturbs the regular deposition of the oncoming layers of the crystal in specific directions, as defined by the hydrogen bonding pattern of the side chain of the substrate. The rate of growth in these directions is thus decreased, leading to changes in crystal morphology. These results, which have been extended to other hydrogen bonded systems (Z.B.-Y., L.A., M.L. and L.L., work in preparation), suggested that crystal habit can be modified in a controlled way by use of appropriate crystal growth inhibitors.

We have applied this concept to polar crystals, racemates and meso compounds to design a new direct method for the assignment of absolute configuration of chiral molecules. Although here we consider only polar crystals. We shall first present a topological model which outlines the requirements for assignment of absolute configuration, and then describe its successful application to Lys.HCl.2H₂O and trans-cinnamoyl-alanine.

Modelling impurity effects on polar crystal growth

We consider a chiral molecule (or a non-chiral molecule adopting a chiral conformation), represented schematically as X-A, packing in a polar crystal whose unique polar axis is parallel to the X-A molecular axis. These requirements can be fulfilled in all chiral polar space groups, among which are P1, P2₁, C2, and

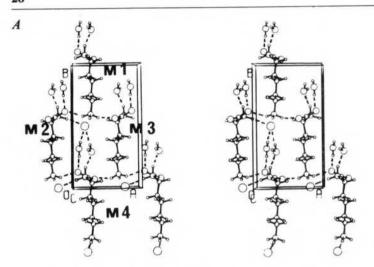

Fig. 1 Packing arrangement of the crystal structure of Llysine \cdot HCl \cdot 2H₂O viewed along the $_{c}$ C-axis. A, stereographic view; B, packing arrangement as delineated by the observed hk0crystal faces.

 $P3_1$. In principle the approach may be extended to any chiral crystal (such as P222, $P2_12_12_1$), in which the molecule X-A is oriented in a general polar direction.

The crystal model is depicted in scheme (1) for a structure appearing in the common polar space group P21. This crystal is delineated by faces f1, f2 in the +b-direction and f3, f4, f5 in the b-direction. By virtue of the crystal (point) symmetry the faces within each pair (f1, f2) and (f3, f5) are related by 2-fold symmetry. The polar nature of the crystal precludes a symmetry relationship between the +b and -b directions. Thus faces within the pairs (f_1, f_5) and (f_2, f_3) cannot be related by symmetry. Consider that in this crystal only A groups emerge at faces f1 and f₂ whereas X groups emerge at faces f₃, f₄, f₅. The essence of the problem is that conventional X-ray diffraction does not provide information as to whether the molecule X-A points in the +b or in the -b direction. In other words, it does not allow one to distinguish between the real crystal scheme (1a) and the hypothetical enantiomeric structure in which the orientation of X-A with respect to the b-axis is opposite scheme (1b).

Applying the two-stage mechanism of adsorption-inhibition, described above, appropriate impurities X-Y or Z-A should influence asymmetrically the growth rate of the crystal along the polar b-axis, thus allowing one to determine whether X-A is directed along the +b- or -b-direction, through selective morphological changes. An impurity X-Y will bind to faces f1 and f2, but not to f3, f4, f5, and once bound, will hinder growth along the +b and possibly other directions, but not along -b in the real crystal of scheme (1) (the opposite would happen in the crystal of scheme (1b)). We would then predict changes in crystal habit involving either an increase of the areas of faces f₁ and f₂ relative to those of other faces of the crystal, or the development of appropriate, additional new faces. The same logic applies to an impurity Z-A which we predict would affect growth of faces f₃, f₄, f₅. The morphological differences between crystals grown in the presence and in the absence of the impurity would then indicate the direction of the modified group in the given crystal, thus establishing the direction of the substrate molecule X-A with respect to the polar axis. Consequently the absolute configuration of the crystal and of the chiral molecular constituents can be derived. Note that the additive need not be chiral and, even if it is, the assignment of absolute configuration of the crystal does not require a knowledge of the absolute configuration of the additive.

Results

(L)Lys.HCl crystallizes from water as a dihydrate in a monoclinic structure $^{15-17}$ of space group P2₁ with Z=2 and a=7.49,

b=13.32, c=5.88 Å, $\beta=97.50^\circ$. The packing arrangement viewed along the c-axis is shown in Fig. 1. The Lys molecules are oriented with respect to the b-axis so that the ε -NH $_3^+$ group is directed along -b, and the amino acid function (NH $_3^+$ C(CO $_2^-$) along +b. Crystals of (L)Lys.HCl.2H $_2$ O grown from water (900 mg cm $_3^-$), cooling in the presence of seeds, 0.5 mg), appear mainly as prisms with an almost triangular section, with the b-axis bisecting the triangle and c directed along the long axis of the prisms (Figs 1B, 2A). The orientations of the molecules relative to the observed hk0 crystal faces are shown in Fig. 1B.

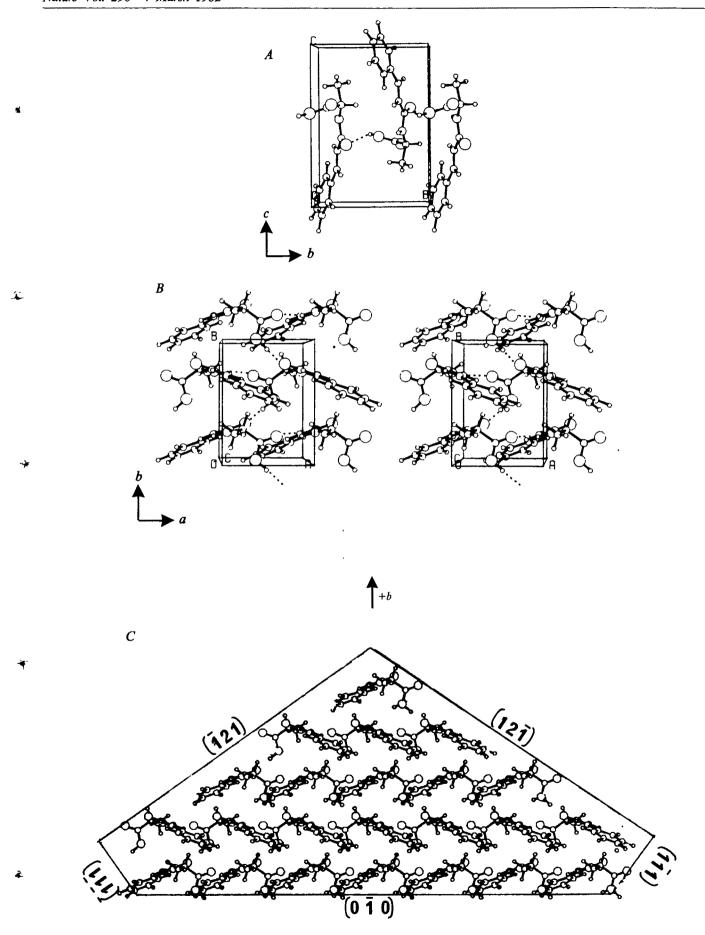

Fig. 3 Packing arrangement of trans-cinnamoyl-L-alanine: A, viewed along the a-axis; B, viewed along the c-axis; C, viewed along the c-axis as delineated by the observed (hk0) crystal faces.

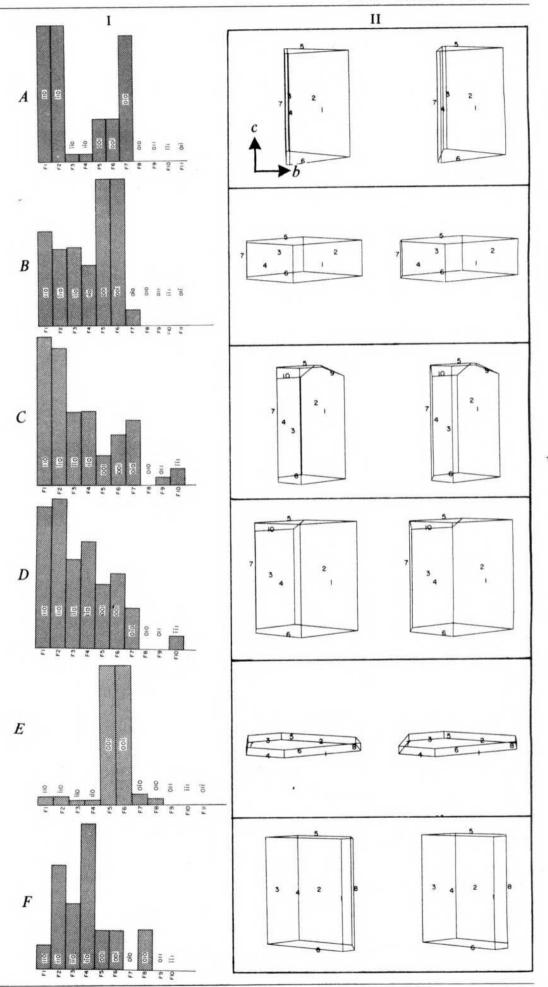

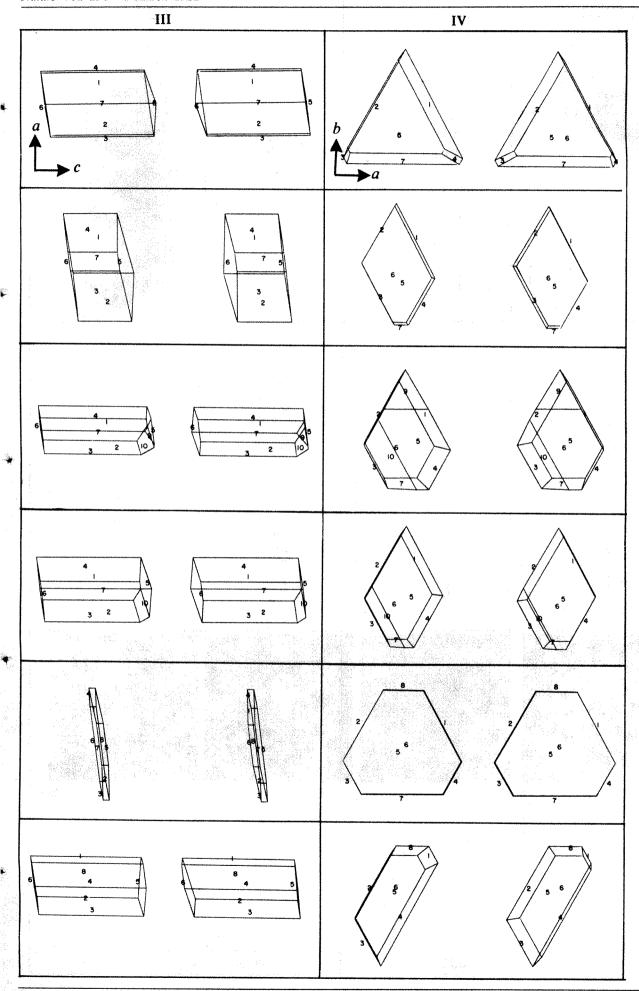

Fig. 4 A comparison between crystals of L-lysine.HCl.2H₂O grown in the absence and presence of additives: A, pure; B, +L-Orn; C, +L-NorVal; D, +L-NorLeu; E, +L-MeLys; F, +ε-aminocaproic acid. I, Histograms describing the areas of the faces. II, III and IV, computer-drawn stereographic pictures of the crystals viewed along axes a, b and c respectively.

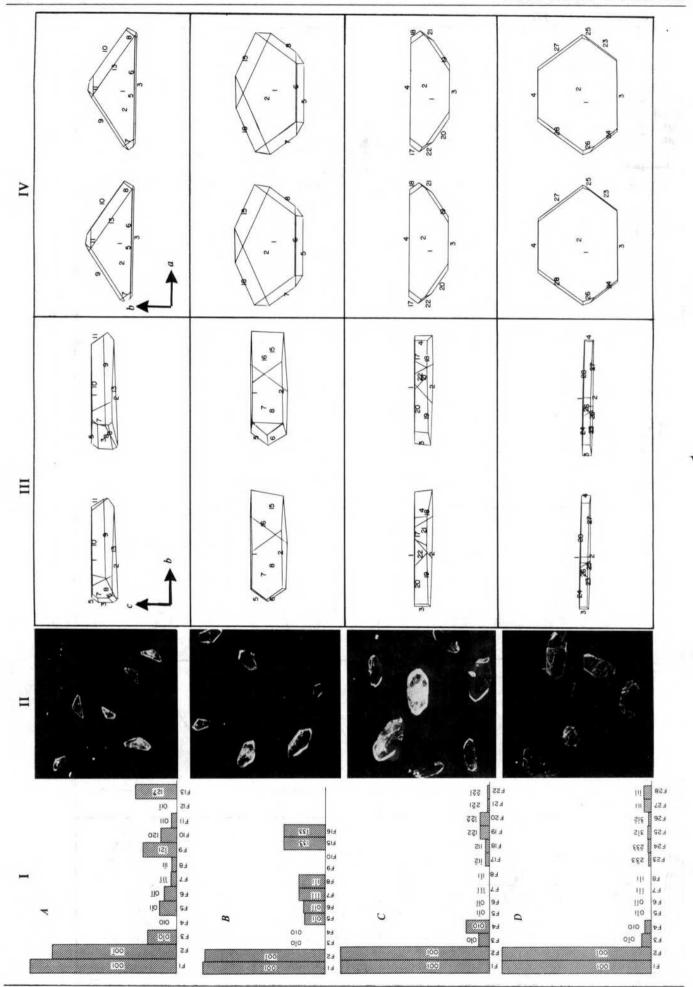

Fig. 5 A comparison between crystals of cinnamoyl L-alanine grown in the absence and presence of additives A, pure; B, +3% methyl ester; C, + trans-cinnamoyl (D)-alanine; D, +trans-cinnamoyl D-serine. I, Histograms describing the areas of the faces. II, Photographs of crystals. III and IV, Computer-drawn stereographic pictures of the crystals viewed along axes a and c respectively.

Bearing in mind the above conclusions, the crystal structure suggested that an impurity with modified carboxyl or α -amino groups will disturb growth along +b but not along -b, whereas modifications in the side chain will, by contrast, disturb growth along -b, but not +b. For both cases we may expect some modification in the a and c directions. (1) L-methyl lysinate (MeLys) and ε -aminocaproic acid (which is non-chiral) and (2) L-ornithine (Orn), L-norleucine (NorLeu), and L-norvaline (NorVal) were selected as additives representative of the two cases. Crystals of L-Lys.HCl.2H2O, were grown from water in the presence of each impurity separately. The concentrations of the additives in solution were: L-Orn.HCl: 200 mg cm⁻³; L-NorLeu: 10 mg cm⁻³; L-NorVal: 10 mg cm⁻³; L-MeLys.HCl: 50 mg cm⁻³; ε -aminocaproic acid: 200 mg cm⁻³. The amounts of additives used in solution were chosen on the basis of the respective solubilities in H₂O, and are always much larger than the amounts found in the bulk of the substrate crystals after crystallization.

The crystals obtained were separated by decantation, dried and examined (Fig. 2B-D). The faces were characterized and the dimensions measured as described previously¹³. The computer-drawn pictures of pure and affected crystals are shown in Fig. 4 together with the histograms of the face areas. The additives L-Orn, L-NorLeu, and L-NorVal inhibit growth along the -b-direction, as indicated by the pronounced increase in the areas of the symmetry-related (110) and (110) faces (see Figs 2B, C and 4B, C, D). This change in crystal habit is primarily a consequence of rupture at the impurity site of the two (ε -amino)N-H···O(carboxyl) H-bonds linking molecule M(1) to M(2) and M(3), related to it through 2_1 -axes (see Fig. 1A). The H-bonded system (ε -amino)N-H···Ck HOH along

The impurity L-MeLys affects growth along the +b-direction inducing formation of the (010) face. Although we could not pinpoint the precise orientation of the O-CH₃ group of the impurity, there can be little doubt that this group would disrupt the H-bonded network along the +b-direction because the substrate CO₂ group participates in several H-bonds along +b. from molecule M(4) to M(1) and M(3) and to two water molecules (Fig. 1). MeLys also affects growth along the c-axis, turning the crystal into (001) plates (Figs 2D and 4E). This change is not surprising in view of a possible rupture of the $(\varepsilon$ -amino)N-H···O(carboxyl) bond interlinking lysine molecules along the c-axis and of the steric hindrance induced by the methyl group of MeLys along the short c-axis. ε -Aminocaproic acid induces formation of the (010) crystal face and thus has a similar effect to MeLys, which may be explained on analogous lines. However, unlike MeLys, this impurity does not affect growth along the c-axis, presumably because no steric hindrance is induced along this direction.

Trans-cinnamoyl-L-alanine

the -b-direction would also be hindered.

Trans-cinnamoyl-L-alanine crystallizes from CHCl₃, MeOH or EtOH in polar crystals of space group P2₁, with a=6.1, b=8.2, c=11.3 Å, $\beta=90.6^{\circ}$. In the crystal^{18,19} (Fig. 3) the molecules are oriented such that the carboxyl O-H participates in an O-H···O(amide) bond whose vector has a major component along the -b-direction, and the C(chiral)-H bond is almost parallel to +b (Fig. 3A). Pure trans-cinnamoyl-L-alanine crystals, grown from CHCl₃ by slow evaporation at room temperature, appear as thin pentagonal (001) platelets, with the symmetry axis b bisecting the pentagon perpendicular to its base (Figs 3C, 5A). Figure 3C shows the orientation of the molecule with reference to crystal faces in the pure crystal. Following the above analysis, the methyl ester of the acid should decrease the

growth rate in the -b-direction. By the same reasoning growth should be inhibited along the opposite direction, +b, using trans-cinnamoyl-D-alanine or trans-cinnamoyl-D-serine as the impurity: binding at the surface of the substrate crystals should be possible for such impurities by virtue of strong H-bonds, but once bound their C(chiral)—CH₃ [or C(chiral)—CH₂OH] group would replace the C(chiral)—H group of the substrate thus hindering growth along the +b-direction. Such a conformation of the impurity molecule would not incur intramolecular steric contacts. Indeed the ease of such an effective interchange of the CH₃ and H substituents at the chiral C atom is demonstrated in the crystal structure of o-chlorocinnamoyl-L-alanine^{18,19}.

Crystals were grown from CHCl₃ in the presence of increasing amounts (1, 3, 5 and 10%) by weight) of these three impurities, in the same conditions as for the pure compounds. The morphologies of these crystals are presented (Fig. 5). The most pronounced change induced by the methyl ester of transcinnamoyl-L-alanine is the large increase in the areas of the symmetry-related $(1\overline{1}1)$ and $(\overline{1}\overline{1}\overline{1})$ faces. Other changes are the formation of the $(0\overline{1}1)$ and $(0\overline{1}\overline{1})$ faces instead of $(0\overline{1}0)$ and replacement of the steep $(\overline{1}21)$ and (120) faces by the shallower $(13\overline{3})$ and $(\overline{1}33)$ faces. The relative increase in areas of these faces is, by and large, proportional to the amount of impurity in solution (1-5%).

We account for the large increase in the area of the $(1\bar{1}1)$ face in terms of the observation that the (carboxyl)O-H···O(amide) H-bond emerges from this face almost perpendicular to it, making an angle of 16° with its normal. Thus the replacement of the substrate group by O-CH₃ at the site of the impurity precludes formation of the O-H···O H-bond and hinders the natural growth perpendicular to the $(1\bar{1}1)$ face, with a subsequent increase in its area.

The impurity trans-cinnamoyl-D-alanine induces formation of the (010) face as shown in Fig. 5 C. This morphological change reflects an inhibition of growth along the +b-direction, as predicted above. A similar morphological change is induced by the additive trans-cinnamoyl-D-serine (Fig. 5D). In the case of trans-cinnamoyl-D-alanine the effect is so pronounced that the (010) face, absent in the pure crystal, is much more developed than the naturally developed (010) face.

Discussion

The experimental findings on lysine and cinnamoyl alanine indicate that it is possible through modification of crystal morphology by tailor-made impurities in appropriate systems, to establish the absolute configuration of the substrate molecule. The present approach differs radically from that of Waser, who tried to ascertain absolute configuration on the basis of the morphology of the pure crystal by comparing the relative ease of attachment of molecules to hemihedral faces $\{hkl\}$ and $\{hkl\}$. The latter approach is full of pitfalls, because the sole difference between the energy of attachment²⁰ to the two faces arises from solvent effects and differences in polarizability and conformation between the crystal-bound molecule at the surface and the to-be-attached 'free' molecule. Effects of these kinds are difficult to quantify. These uncertainties do not affect our approach because the change in crystal habit originates essentially from the difference in the ease of approach of the to-beattached molecule to the same face in the poisoned and unpoisoned crystals. Moreover, the reliability of the method is increased by observing a progressive change in crystal habit as a result of increasing concentration of impurity in solution, and by a cross-check of the assignment by using various impurities, appropriately designed, so that they will affect stereoselectively either polar growth direction.

The method is not limited to chiral crystals, but is applicable also to racemic or meso compounds, with certain desired

packing features, for assignment of the absolute configuration of the chiral additive. This extension is based on the fact that, in contradistinction to chiral crystals, in racemic compounds comprising chiral R and S moieties, one can specify unambiguously the chirality of the moiety which emerges from a given crystal face. Crystallization of such a racemic crystal poisoned with chiral impurity may affect enantioselectively one of the pair of enantiotopic crystal faces. From the change in crystal habit it may be possible to fix the absolute configuration of the additive. An analysis of the packing requirements and application of this method to serine-threonine will be presented elsewhere21

The rules of morphological changes, as outlined here, also

apply to solid solutions, with the advantage that one may there be able to locate precisely the atomic positions of the occluded guest additive by X-ray diffraction. This will eventually allow us to study these phenomena on a quantitative basis, leading hopefully to a better understanding of the correlation between molecular structure and crystal morphology.

We thank Professor Duilio Arigoni for his prompting (since 1969) that there must be a simple way to extract absolute configuration of chiral molecules from morphology, also Professor M. D. Cohen for discussions and Sarah Ariel for the crystal structure coordinates of cinnamoyl-L-alanine, and the US/Israel Binational Science Foundation, Jerusalem, and the Volkswagen Stiftung Foundation for financial support.

A monoclonal antibody defining antigenic determinants on subpopulations of mammalian neurones and Trypanosoma cruzi parasites

J. N. Wood*, L. Hudson, T. M. Jessell* & M. Yamamoto*

Departments of Immunology and Pharmacology, St George's Hospital Medical School, London SW17 0RE, UK

An IgM λ class monoclonal antibody raised against membranes from rat dorsal root ganglia defines a novel antigenic determinant expressed by subpopulations of mammalian central and peripheral neurones. In the presence of complement the antibody is cytotoxic to mammalian neurones in vitro. The same antibody labels Trypanosoma cruzi, the protozoan responsible for Chagas' disease. Classes of mammalian neurones and cardiac muscle that are labelled by the antibody are known to degenerate in Chagas' disease. The common neuronal and trypanosomal antigens recognized by the antibody may therefore be important in pathogenic events underlying this disorder.

CHAGAS' DISEASE results from infection with the protozoan Trypanosoma cruzi, affects an estimated 12 million people in Latin America¹ and is characterized by extensive neuronal degeneration. In the peripheral nervous system, there is a massive degeneration of sympathetic², parasympathetic³ and enteric^{4,5} neurones. Lesions of Purkinje neurones in the cerebellar cortex have been reported^{5,6} and there is also significant degeneration of cardiac muscle in both the acute and chronic stages of the disease7.

Although neuropathy does not result from direct parasite invasion, the precise mechanism underlying neuronal degeneration is still unclear. It has been suggested that Chagas' disease may have an immunological basis, consistent with the destruction of cardiac and neuronal tissue by an autoimmune mechanism^{8,9}. One explanation for the origin of this autoreactivity is that the host and parasite share common antigenic determinants, such that the development of anti-parasite immunity allows cross-reactivity with self components.

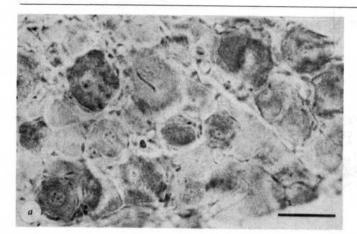

* Present addresses: Department of Experimental Immunobiology, Wellcome Research Laboratories, Beckenham, Kent BR3 3BS, UK (J.N.W.); Department of Neurobiology, Harvard Medical School, Boston, Massachusetts 02115, USA (T.M.J.); College of Medical Technology, University of Tsukuba, Niihari-gun, Ibaraki, Japan (M.Y.).

Previous studies have demonstrated that sera from patients with T. cruzi infection contain antibodies that recognize mammalian vascular endothelial cells¹⁰, components of peripheral nerve, possibly Schwann cells¹¹, the plasma membrane of striated muscle and endothelial cells¹² and certain peripheral and central neurones¹³. However, in these studies the nature of the antigenic stimulus is unknown.

We report here that a monoclonal antibody, generated against mammalian dorsal root ganglia, exhibits a unique specificity for subpopulations of central and peripheral neurones and also recognizes an antigenic determinant on the protozoan T. cruzi. Strikingly, all classes of neurones we have examined that are known to undergo degeneration in Chagas' disease express this antigenic determinant. In addition, cardiac muscle is stained by the antibody whereas skeletal muscle, which is unaffected in Chagas' disease, is not.

Production and characterization of antibodies

With the original aim of generating antibodies that might provide markers for subpopulations of primary sensory neurones, dorsal root ganglia were dissected from 7-day-old CD rats (Charles River Breeding Laboratories). Ganglia pooled from

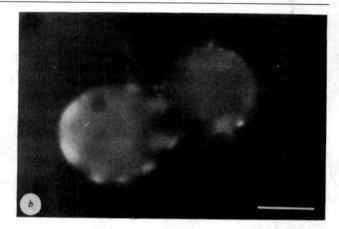

Fig. 1 Immunocytochemical labelling by CE5 of rat dorsal root ganglion neurones in fixed sections and dissociated cell culture. For staining of fixed sections, rats were anaesthetized with ether and perfused via the aorta with 500 ml of 4% paraformaldehyde in 0.1 M phosphate buffer (pH 7.4) at room temperature. The brain, spinal cord and dorsal root ganglia were removed and placed overnight at 4 °C in 0.1 M phosphate buffer containing 30% w/v sucrose. 30-µm sections were cut with a freezing microtome and incubated in CE5 hybridoma supernatant diluted 1:1 with PBS (pH 7.4) for 18-24 h at 4 °C. Sections were then washed three times with PBS and incubated for 20 min with either horseradish peroxidase- or FITC-conjugated rabbit anti-mouse IgG (Litton Bionetics) diluted 1:25 with PBS. Sections processed for fluorescence were then washed three times in PBS mounted on glass slides, and viewed on a Leitz Ortholux II microscope equipped with epifluorescence illumination. Photographs were taken with 2-min exposures using 400 ASA film. For peroxidase immunocytochemistry, sections were washed three times in 0.05 M Tris-HCl (pH 7.6) after removal of second antibody and incubated with 0.05% diaminobenzidine and 0.002% H₂O₂ in 0.05 M Tris-HCl for 10-20 min. Stained sections were dehydrated in alcohol and xylene, mounted in Permount and viwed under bright field and interference contrast optics. a, Immunoperoxidase staining of sensory neurone cell bodies in sections of cervical dorsal root ganglia. Immunoreaction product is present throughout the cytoplasm although membrane associated staining can also be observed. In many sections, large neuronal cell bodies appeared more densely stained than small neurones. Stained fibres can also be seen within the section although satellite and other non-neuronal cells appear unstained. Scale bar, 50 µm. b. Immunofluorescent staining of rat dorsal root ganglion neuronal cell bodies, grown in dissociated cell culture for 10 days. Dorsal root ganglia were removed from rat embryos at 19 days of gestation, incubated with 0.05% trypsin and 0.01% collagenase (Worthington type IV) for 20 min at 37 °C and dissociated by trituration. Cells were plated onto collagen and fibronectin-coated 35-mm tissue culture dishes in Ham's F12 medium containing 7.5% heat-inactivated rat serum, 4% 17-day rat embryo extract, 2 mM glutamine, essential vitamins, 5,000 U ml⁻¹ penicillin and streptomycin, 44 mM glucose and 1 µg ml⁻¹ purified nerve growth factor. Cultures were fed every 2-3 days and treated with cytosine arabinoside (10-5 M) for 24-28 h soon after plating. Cultures were fixed with 4% paraformaldehyde in 0.1 M phosphate buffer, pH 7.4, and processed for immunofluorescence as described above. Patchy staining of two sensory neurone cell bodies can be observed with staining apparent in both the cytoplasm and in association with the surface membrane. Scale bar, 20 µm.

six rats were sectioned in a tissue chopper and homogenized in 0.05 M Tris-HCl (pH 7.6) with a Dounce pestle, followed by centrifugation at 2,000g for 10 min. The resulting supernatant was then centrifuged at 50,000g for 30 min and the crude membrane pellet used for immunization.

Six-week-old female BALB/c mice were injected intraperitoneally with 0.2 ml of the membrane suspension (10 mg ml⁻¹) in phosphate-buffered saline (PBS pH 7.4) emulsified 1:1 with Freund's complete adjuvant. Injections were repeated twice at 14-day intervals. Three weeks later a final injection was performed, without adjuvant, and the spleens from immunized mice were removed after a further 3 days. Lymphocytes were fused¹⁴ with X63.Ag 8.653 myeloma cells¹⁵. Hybrid clones were screened after 10 days and positive wells were cloned three times by limiting dilution.

Hybridoma supernatants were screened by indirect immunofluorescence using fluorescein isothiocyanate (FITC)conjugated rabbit anti-mouse IgG on 30-µm transverse sections of the dorsal root ganglia and spinal cord of rats fixed by perfusion with 4% paraformaldehyde in 0.1 M phosphate buffer (pH 7.4). Of 288 hybridoma supernatants examined, 24 exhibited positive staining of neuronal cell bodies and an additional 4 stained radial glial fibres. One supernatant, designated CE5, labelled dorsal root ganglion neurones (Fig. 1a), motoneurone cell bodies (Fig. 2c) and large-diameter neurones within laminae IV and V of the dorsal horn with little or no staining of neuronal cell bodies in laminae I-III. Numerous neural processes were also observed in the spinal grey matter although there was little or no labelling of the white matter. Hybrid cells secreting antibody CE5 were recloned three times and all subsequent studies were performed on tissue culture supernatant. Antibody CE5 was found to be of the 1gM A subclass when tested by indirect immunofluorescence using subclass-specific antisera or after SDS-polyacrylamide gel electrophoresis of 35S-methionine-labelled immunoglobulin (gels run in reducing conditions with known 1gG and 1gM markers16).

Subpopulations of mammalian neurones stained by CE5

The distribution of cells labelled by CE5 was determined by visualizing antibody-binding sites with FITC- or peroxidase-conjugated rabbit anti-mouse IgM (as detailed in Fig. 1 legend).

In sections of adult rat dorsal root ganglion, the cytoplasm and external membrane of sensory neurones was labelled, whereas non-neuronal cells were not (Fig. 1a). A similar distribution and selectivity of labelling were seen in dorsal root ganglion cells grown in dissociated culture (Fig. 1b). Although insufficient CE5 was bound to the surface of viable neurones to enable detection by indirect immunofluorescence¹⁷, sufficient antibody was bound to activate complement and mediate lysis of >90% of sensory neurones. Significantly, non-neuronal cells in these cultures were unaffected by exposure to CE5 plus complement, consistent with the failure of CE5 to label non-neuronal cells by indirect immunofluorescence.

In 30-µm transverse sections of adult rat cerebellar cortex, Purkinje neurones were the only cells labelled (Fig. 2a) and showed intense staining of both the soma and dendritic tree, with occasional axonal labelling. Throughout the cerebral cortex, staining was observed in the cell bodies of pyramidalshaped neurones within layer V (Fig. 2d) and their basal and apical dendrites (Fig. 2e). The cell bodies of pyramidal-shaped neurones within layers II and III were faintly stained in some but not all cortical areas. Within the hippocampus, occasional pyramidal cell bodies and their dendrites were stained, as were the majority of granule cell bodies and mossy fibres in the dentate fascia. In the olfactory bulb, labelling was observed in mitral cell bodies and their dendrites projecting through the external plexiform layer and terminating in superficial glomeruli (fig. 2f), while the cell bodies of intrinsic olfactory neurones were unstained. A complex pattern of neuronal labelling with CE5 was observed in other regions of the central nervous system (to be described in detail elsewhere), although staining in all

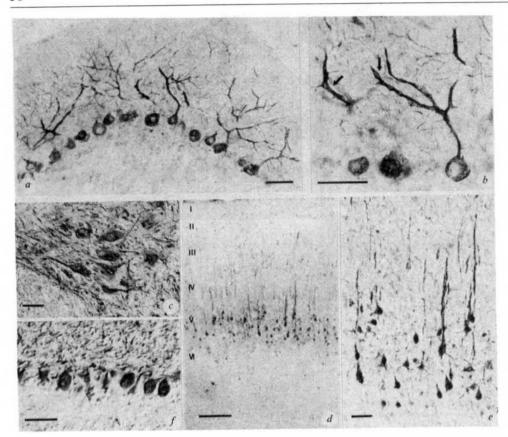

Fig. 2 Immunocytochemical localization of neurones in the rat central nervous system labelled with CE5. Immunoperoxidase staining procedures were carried out as described in Fig. 1 legend, a, Selective labelling of Purkinje neurone cell bodies and dendrites in rat cerebellar cortex. Scale bar, 100 µm. b, High power micrograph showing the cylindrical labelling pattern (arrows) in oblique sections through Purkinje neurone dendrites, suggesting an association of the antigen with the surface membrane of the dendrite. The Purkinje neurone cell body, however, is labelled throughout the cytoplasm. Labelled axons can occasionally be seen projecting through the granular layer. Scale bar, 100 µm. c, Staining of the cell bodies and initial processes motoneurones, and other neuronal elements within the ventral horn of the rat cervical spinal cord. Scale bar, 50 µm. d Selective labelling of neurones in or near layer V of the rat occipital cortex. Dendrites can be seen projecting to more superficial layers. Scale bar, 200 μm. e, High power micrograph showing the pyramidal appearance of labelled cell bodies within rat occipital cortex. Numerous superficial dendrites are stained and also occasional radial dendrites projecting within layer V Scale bar, 50 µm. f, Immunoperoxidase staining of mitral cell bodies and dendritic profiles in the olfactory bulb. Scale bar, 50 µm.

regions was confined mainly to neurones with axons projecting beyond their nucleus of origin.

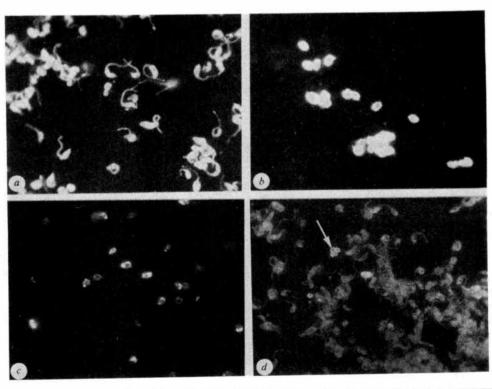

The specificity of neuronal labelling provides few clues, in itself, to the functional significance of CE5-defined antigens. Antigenic expression is clearly unrelated to the transmitter specificity of individual neurones and occurs in neurones derived from both the neural tube and neural crest. Other monoclonal antibodies recognizing subpopulations of vertebrate and invertebrate neurones reveal a completely different distribution of labelled cells¹⁷⁻²¹. In addition, although cerebellar Purkinje neurones and some but not all of the central

neurones stained by CE5 are also stained by polyclonal antisera directed against the calcium-binding proteins calmodulin²², parvalbumin²³ and vitamin D-dependent calcium-binding protein²⁴, CE5 did not react with any of these proteins. Antibody CE5 therefore seems to define a novel antigenic determinant in the mammalian nervous system.

Staining of trypanosomes by CE5

Of 11 monoclonal antibodies raised against rat neurofilaments, neuroglial cells or other neural antigens, only CE5 and its subclones stained formaldehyde-fixed *T.cruzi* when examined

Fig. 3 Staining of T.cruzi (Y Strain) organisms with CE5 monoclonal antibody. a, Formaldehyde-fixed epimastigotes showing homogeneous cytoplasmic fluorescence. b, Formaldehyde-fixed amastigotes showing bright fluorescence associated with the surface membrane. c, Viable amastigotes stained in suspension; living epimastigotes gave no reaction with CE5. d, Batch culture of epimastigotes containing a low percentage of amastigotes, after formaldehyde fixation. Epimastigotes gave typical cytoplasmic fluorescence whereas in amastigotes (arrowed) the antigen detected by CE5 is limited to the cell-surface membrane. As a specificity control, parasites were also treated with an IgM monoclonal antibody against dinitrophenol or with ascitic fluid containing MOPC 104E myeloma IgM. Positive staining was only observed with CE5.

by indirect immunofluorescence using FITC-conjugated antiimmunoglobulin serum. Epimastigotes of *T.cruzi* (Y strain) and *Herpetomonas samuelpessoai* were obtained from culture in Warren's medium²⁵. Non-motile amastigotes of *T.cruzi* were obtained from cultures of a murine thigh muscle tumour (S2) infected with trypomastigotes derived from the plasma of acutely infected mice. *T.brucei* trypomastigotes were isolated from the plasma of acutely infected rats. Whereas both epimastigotes and amastigotes of *T.cruzi* exhibited bright immunofluorescent staining (Fig. 3a, b), *T.brucei* and *H.samuelpessoai* showed no staining with CE5.

In addition, the various developmental stages of T.cruzi exhibit differential staining patterns with CE5. Paraformaldehyde-fixed epimastigotes reacted with CE5 to produce a homogeneous cytoplasmic staining (Fig. 3a) whereas staining of fixed amastigotes was only associated with the cell-surface membrane (Fig. 3b). The significance of this observation in relation to the manifestation of Chagasic symptoms would be greatly enhanced if this antigen was present on the surface of the parasite and thus directly available to the immune response. To examine this possibility, viable amastigotes and epimastigotes were incubated sequentially with CE5 and FITC-conjugated rabbit anti-mouse 1gM. The surface membrane of viable amastigotes exhibited a bright immunofluorescence (Fig. 3c) whereas no staining was observed on the surface of viable epimastigotes. In the conditions of batch cultures used in these experiments, some epimastigotes showed spontaneous transformation into amastigotes. These viable amastigotes also exhibited intense membrane staining (Fig. 3d).

CE5-defined antigens and Chagas' disease

In the peripheral nervous system, one of the main histological features associated with T. cruzi infection is periganglionitis and degeneration of intrinsic myenteric neurones in the gastrointestinal tract⁵. In fixed whole-mount preparations of guinea-pig submucosal plexus²⁶ treated with CE5, clusters of neuronal cell bodies exhibited bright immunofluorescence within the cytoplasm and external membrane (Fig. 4a). Staining of neuronal processes within the submucosal plexus was also observed. However, without prior removal of the extrinsic sensory nerves projecting to the gut, it is not possible to determine whether these fibres originate from enteric neurones or from vagal and spinal sensory neurones.

The acute and chronic phases of Chagas' disease are characterized by the degeneration of striated muscle fibres in the heart, whereas skeletal muscle does not appear to be affected²⁷. Staining of cardiac muscle fibres appeared as intense crossstriations (Fig. 4c). The spacing between stained bands was 2.2–2.4 μ m and sequential examination under bright field and phase contrast optics revealed staining located at the junction of A and I bands. The same pattern of staining was observed in glycerinated muscle fibres, suggesting that the antigen is closely linked to structural proteins in the muscle fibre. In contrast, CE5 did not stain skeletal muscle fibres removed from the rat tibialis anterior muscle.

The antigenic determinants recognized by CE5 are also present in the human nervous system; Purkinje neurones were stained selectively in postmortem human cerebellum (Fig. 4c). Although little is known about the central neuropathology in patients suffering from Chagas' disease, the only central neurones so far reported to undergo degeneration are cerebellar Purkinje neurones⁵.

Antigens recognized by CE5

The staining of Purkinje neurones in rat cerebellum could be abolished by preabsorbing CE5 hybridoma supernatant with an equal volume of formaldehyde-fixed *T.cruzi* epimastigotes, confirming that a common antigenic determinant is therefore expressed by mammalian neurones and *T.cruzi* parasites. If this determinant is relevant to the neuropathology associated with Chagas' disease, the serum of mammalian hosts infected

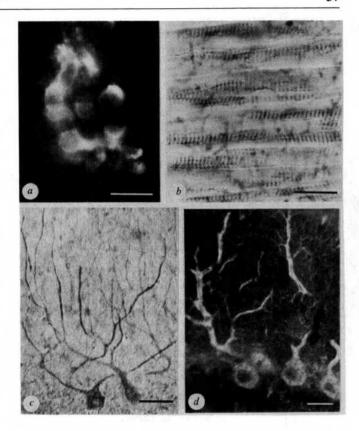

Fig. 4 CE5 labelling of mammalian cells known to degenerate in Chagas disease. a, Immunofluorescent labelling of neuronal cell bodies in ganglia located in the submucosal plexus of the guinea pig. Whole-mount preparations of the guinea pig submucosal nerve plexus²⁶ were fixed in 4% paraformaldehyde in 0.1 M phosphate buffer for 30 min, washed and processed for indirect immunofluorescence as described in Fig. 1 legend. Scale bar, 50 µm. b, Immunoperoxidase labelling of cross-striations in cardiac muscle fibres in 30-um sections of formaldehyde-fixed rat heart exposed to CE5. Consistent staining of cross-striations can be observed. Apparent staining in the longitudinal axis reflects folds in the muscle fibre. Scale bar, 50 μm. c, Interference contrast micrograph showing immunoperoxidase staining of two Purkinje neurones in human cerebellar cortex. Human postmortem cerebellar cortex was obtained within 12 h of death and fixed by immersion for 24-48 h in 4% paraformaldehyde, washed for 24 h and processed for immunocytochemistry as described in Fig. 1 legend. Note the absence of staining of other neurones in the molecular layer. Scale bar, 100 µm. d, Immunofluorescent staining of rat cerebellar Purkinje neurones after exposure of cerebellar sections to sera obtained from mice infected 90 days previously with T.cruzi parasites. Sera from infected mice were diluted 1:10 with PBS and applied to cerebellar sections for 18-24 h at 4 °C. After extensive washing, sections were incubated with FITC-conjugated anti-mouse immunoglobulin (Miles) diluted 1:50 for 30 min at room temperature, washed and mounted on glass slides. Intense staining of the cell bodies and dendrites of the Purkinje neurones can be seen, with less intense staining of other cellular elements in the molecular layer. Scale bar, 50 µm.

with *T.cruzi* might be expected to contain circulating antibodies directed against the same determinant. Sera from mice infected with *T.cruzi* for 14, 90 or 210 days were therefore used to stain sections of rat cerebellum. An intense labelling of the cell bodies and dendrites of Purkinje cells was seen, with additional, weaker staining of other cells in the molecular and granular layers (Fig. 4d). Sera from uninfected mice gave no specific staining.

The determinants in mammalian cells and T.cruzi that are recognized by CE5 were analysed using the immune blotting technique of Towbin et al.²⁸. All rat neuronal tissue, of central or peripheral origin, produced a similar pattern (Fig. 5, lanes c, d). A predominant immunoreactive band with an apparent molecular weight (M_r) of $\sim 60,000$ was observed together with a minor band of $M_r \sim 32,000$ and very faint bands $M_r > 70,000$.

Extracts of cardiac muscle revealed an intense band of $M_r \sim 20,000$ (Fig. 5, lane e) whereas skeletal muscle showed no stained bands, in accord with the results found by immunocytochemistry. Several very faint bands were also

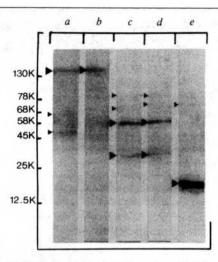

Fig. 5 Autoradiographic localization of proteins stained by CE5 after polyacrylamide gel electrophoresis and electrophoretic transfer of proteins onto nitrocellulose. Samples (50-100 µg) were boiled for 2 min in 10% SDS containing 2% \(\beta\)-mercaptoethanol and electrophoresed in 10% polyacrylamide gels in the presence of SDS. After electrophoresis, the gel was blotted onto a nitrocellulose sheet for 2 h at 12 V. The sheet was then incubated overnight in PBS containing 3% haemoglobin. CE5 tissue culture supernatant diluted 1:10 in PBS-haemoglobin was then applied to the sheet for 60 min. After six washes in PBS, ¹²⁵I-labelled rabbit anti-mouse globulins (5×106 c.p.m.) in PBS-haemoglobin was applied to the sheet for 60 min, and the sheet then washed a further six times in PBS. The dried sheet was exposed for 5-15 days at -70 °C using Kodak X-omat H film. Lane a, epimastigotes; lane b, amastigotes; lane c, 7-day rat dorsal root ganglia; lane d, rat cerebellum; lane e, rat heart. The positions of molecular weight standards are indicated.

observed in extracts of liver, kidney and testis and a very faint reaction was found in these immunochemistry. The staining patterns produced by extracts of T.cruzi epimastigotes and amastigotes were distinct, with bands in a molecular weight range of 50,000-100,000 (Fig. 5, lanes a, b). Extracts of T.brucei, however, exhibited no immune staining, again in agreement with immunofluorescence studies.

The complex banding pattern shown by CE5 may reflect a common amino acid sequence in distinct proteins, breakdown products of a single large protein or a carbohydrate moiety common to several glycoproteins. Exposure of rat cerebellar sections to neuraminidase, mannosidase or periodate oxidation at pH 7.4 (ref. 29) did not affect the staining of Purkinje neurones by CE5. Similarly, incubation in the presence of 100 mM α-methyl mannoside, sucrose, galactose or mannose did not reduce the binding of CE5 to Purkinje neurones. It is therefore probable that the CE5-defined antigen is a polypeptide structure present in several different proteins which share a common epitope. Such complexity in staining patterns obtained with monospecific antibodies is not unique. Monoclonal antibodies to glial fibrillary acidic protein³⁰, and to Thy 1.1 (ref. 31) have recently revealed unsuspected antigenic crossreactivity between distinct proteins.

Conclusions

Although previous serological studies 10-13 have suggested that mammalian neurones, cardiac muscle and T.cruzi organisms might share common antigenic determinants, the identification of these antigens using monoclonal antibodies provides a more reproducible basis for future studies. At present, we have no direct evidence that the cross-reactive antigenic determinant recognized by CE5 is involved in the generation of Chagasic lesions. Previous experimental measurements of cell-mediated immunity against cardiac and neuronal antigens showed that a significant degree of autoimmunity was attained only after acute phase degeneration of cardiac neurones had occurred. The late appearance of anti-self-reactivity was taken as evidence that autoimmunity was the result of the pathogenic process and so could not be involved in its initiation. Although autoimmunity provoked by cross-reactive structures might still have a secondary role in the development of Chagasic lesions, the description of anti-neuronal autoantibodies soon after infection and coincident with neuronal destruction32 suggests that an antibody-mediated mechanism might initiate or amplify acuteand chronic-phase lesions in cardiac or neuronal cells.

The availability of CE5 antibody should allow a direct assessment of the role of cross-reactive antigens in the development of Chagasic lesions. For example, proteins expressing the antigen could be purified from mammalian cells or T.cruzi organisms using affinity columns and injected in mice. The appearance of Chagasic lesions would provide strong evidence for their involvement in the disease. It will also be important to determine the effect of central or peripheral administration of CE5 antibody to normal or T.cruzi-infected mice. In infected mice, it is difficult to predict the outcome of CE5 treatment: the result might be parasite and/or antigen clearance with consequent disease amelioration, or alternatively increased neuronal and cardiac damage with disease exacerbation.

The present report may have important implications for the clinical study of Chagas' disease. If the similarity in neuronal staining in rat and human brain extends beyond the cerebellum, it may be appropriate to examine the central neuropathy associated with Chagas' disease in more detail.

Only 1 of 11 antibodies raised against mammalian neural antigens has revealed a cross-reactivity with T.cruzi. further studies using monoclonal antibodies directed against peripheral and central neurones will reveal whether other shared determinants exist and may also provide a greater variety of immunological probes with which to study Chagas' disease.

Regulation of metallothionein-thymidine kinase fusion plasmids injected into mouse eggs

Ralph L. Brinster*, Howard Y. Chen*, Raphael Warren†, Aparna Sarthy† & Richard D. Palmiter†

* Laboratory of Reproductive Physiology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA † Howard Hughes Medical Institute Laboratory, Department of Biochemistry, University of Washington, Seattle, Washington 98195, USA

A plasmid was constructed with the promoter/regulatory region of the mouse metallothionein-I gene fused to the structural gene of herpesvirus thymidine kinase. When mouse eggs were microinjected with this plasmid and incubated with cadmium (a natural inducer of metallothionein gene transcription) thymidine kinase activity increased ~ 10 -fold compared with control eggs not exposed to cadmium. Analysis of a set of deletion mutants revealed that the minimum sequence required for cadmium regulation lies within 90 nucleotides of the transcription start site.

METALLOTHIONEINS (MTs) are ubiquitous proteins of vertebrates and invertebrates that bind heavy metals and are thought to be involved in zinc homeostasis and resistance to heavy metal toxicity¹. The metallothionein-I (MT-I) gene is controlled at the transcriptional level by heavy metals and by glucocorticoid hormones²⁻⁴. To ascertain which sequences are involved in transcriptional regulation, an assay system is required which allows faithful transcription and responds to regulatory molecules. There are currently three basic approaches: cell transformation⁵⁻⁹, cell-free transcription^{10,11} and microinjection of DNA into cells. Plasmids containing intact eukaryotic genes or various mutations created from them in vitro have been injected into the germinal vesicle of frog oocytes to assess the nucleotide sequences required for synthesis of functional mRNAs encoding histones¹², globin¹³, ovalbumin¹ and thymidine kinase¹⁵. Mouse oocytes have been used to study the expression of injected 5S ribosomal genes¹⁶ and mammalian tissue culture cells have been transformed by microinjection of DNA^{17,18}. DNA injected into fertilized mouse eggs may be retained in the adults that develop after reimplanting the eggs into foster mice and in some cases the foreign DNA is expressed 19-23. However, use of mammalian cells for quantitative analysis of transient expression of microinjected plasmids has not previously been reported.

Here we establish the usefulness of microinjecting plasmids into mouse ova as a convenient system for studying transcriptional regulation. The major advantages of this system are that it is homologous to the promoter under study, which should optimize the chances for faithful transcription and regulation, and it is rapid compared with cell transformation. To distinguish transcription originating from the injected genes from that of the endogenous genes, we have fused the mouse MT-I gene promoter and 5'-flanking region to the thymidine kinase (TK) gene of herpes simplex virus (HSV). Viral TK is readily assayed and can be distinguished from endogenous TK^{24,25}. Our results indicate that the MT-I promoter in the fusion plasmid is as effective as the normal HSV TK promoter in allowing synthesis of functional TK when injected into fertilized mouse ova. Furthermore, the MT-I promoter and adjacent DNA sequences respond to Cd and regulate the production of viral TK.

Expression of viral thymidine kinase in mouse ova

In the first experiments, TK activity was monitored by measuring the incorporation of ¹²⁵I-deoxycytidine (¹²⁵I-dC) into DNA. This assay exploits the fact that the HSV TK can phosphorylate ¹²⁵I-dC whereas the mammalian enzyme cannot²⁴; hence, the

Table 1 HSV TK activity in mouse fertilized one-cell eggs injected with various plasmids

Fertilized one-cell ova were flushed from the oviduct using Brinster's medium. The morning of day 1 of pregnancy. Cumulus cells were removed from ova with hyaluronidase (300 U mi⁻¹), and the ova were washed free of debris and enzyme before manipulation. For injection, the ova were transferred to a depression slide in Brinster's medium containing 5 µg mi⁻¹ cytochalasin B and held in place using a blunt pipette while the tip of the injector pipette was inserted through the zona pellucida and vitellus and into the cell nucleus. The DNA solution in the injector pipette was slowly discharged into the nucleus using a syringe connected to a micrometer. The larger pronucleus (male) of the fertilized ovum was injected with ~2 pl of plasmid solution. The injection volume was estimated from the increase in diameter of the nucleus. After injection the ova were washed free of cytochalasin and returned to the same medium used for collection. When the injections were completed the ova were incubated for 22 h in 25 µl of medium. The plasmids injected were: pBR322, the vector plasmid into which the genes were cloned; pMT, which contains the mouse MT-12 gene; pTK, which contains HSV TK27; pMT-TK, which contains both the MT-I and HSV TK structural gene (Fig. 1).

contains the promoter of MT-I fused to the HSV TK structural gene (Fig. 1).

* Values are c p.m.+s.e.m of ¹²⁵I-dC (0 5 µCi; >700 Ci mmoi⁻¹; NEN) incorporated into DNA by 25 ova during a 22 h incubation period

† TK assays were performed in the following manner. After injection of the plasmid, the ova were incubated for 22 h in Brinster's medium then transferred to 20 μ l of hypotonic buffer (10 mM KCl, 2 mM MgCl₂, 10 mM Tris-HCl, pH 7.4, 1 mM ATP, 10 mM β -mercaptoethanol, 50 mM ϵ -aminocaproic acid and 1 mg ml⁻¹ bovine serum albumin)²⁹. The cells were frozen and thawed three times and 20 μ l of reaction mixture (150 mM Tris-HCl, pH 7.5, 10 mM ATP, 10 mM MgCl₂, 25 mM NaF, 10 mM β -mercaptoethanol) were added followed by 5 μ l of water containing 5 μ Ci ³H-thymidine (80 Ci mmol⁻¹; NEN). The mixture was incubated for 2 h at 37 °C, and the ³H-TMP produced was measured by adsorption on to DE-81 paper and subsequent scintillation counting ^{30.31} The values are c.p.m. + s.e.m. of ³H-TMP formed by 25 ova injected with the indicated number of plasmids and incubated for 22 h before assay.

background is very low. Table 1 compares TK activity measured after injecting a few thousand copies of plasmids pBR322, pMT (which contains a 3.8 kilobase (kb) MT-I gene fragment²⁶ inserted into the EcoRI site of pBR322), pTK (which contains a 3.5-kb HSV TK fragment²⁷ inserted into the BamHI site of pBR322), pMT-TK (which contains both MT-I and TK genes²³) and pMK (which has the MT-I gene promoter and 5'-flanking region fused to the TK gene²³; the predicted DNA sequence around the fusion site is shown in Fig. 1). Table 1a shows that incorporation of 125 I-dC into DNA during a 22 h incubation was the same as background when pBR322 or pMT were injected, but increased at least 10-fold when plasmids containing an intact TK gene were injected. A similar high level of 125 I-dC incorporation was observed when pMK was injected. Significant incorporation of ¹²⁵I-dC was detected with as few as 20 molecules of pMK injected per ovum. Table 1a indicates, however, that incorporation of ¹²⁵I-dC was not linearly related to plasmid copy number injected; in other experiments, injection of 20,000

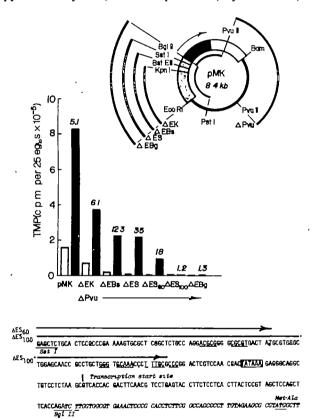

Fig. 1 TK activity generated from various 5'-deletion mutants of pMK. The plasmid is shown at the top. It was generated by restriction pMT-TK with genes, followed by ligation of the MT-I 5' sequences to the TK structural gene²³ The mouse DNA sequence of pMK is referred. BglII, which cuts just upstream of the initiation codon of both MT-I and TK gene²³ The mouse DNA sequence of pMK is stippled, the HSV TK structural gene solid, the 3' HSV sequences are open, and the pBR322 sequences are shown as a solid line. The arrow indicates the direction of transcription. The Puull fragment of pMK was removed as shown by ΔPvu, then a series of deletions were made that extend from EcoRI toward the 5 end of the TK gene. The Ssfi, BstEII and KprI sites he ~150, 340 and 600 bp 5' of the transcription start site, respectively Bal31 was used to extend deletions from Sril site towards the TK gene. In each case an EcoRI linker was inserted and then ligated to the original EcoRI site to create deletions that extend from EcoRI to the positions indicated by the arrows (±5 bp) above the DNA sequence shown at the bottom; the end points were mapped by acrylamide gel electrophoresis of RsaI/EcoRI digests. The MT-I sequence³⁵ between SsI and BgIII is shown fused to the HSV TK sequence³⁴ at the BgIII site. Two palindromes, the TATAAA box, the transcription start site and the initiation codon for TK are indicated Approximately 2,500 molecules of each plasmid were microinjected; TK activity was measured 22 h later as described in Table 1b legend. The results are the means of two experiments with each deletion mutant. Eggs were incubated with (solid histograms) or without Cd (open histograms) for 22 h before TK assay. The numbers over the histograms indicate the ratio of TK activity with and without Cd. The background TK activity of the eggs (2,000-5,000 c.p.m.) has not been subtracted The activities of mutants ΔES_{100} and ΔEBg are not significantly different from background.

or 200,000 copies of pMK gave no more incorporation than injection of 2,000 copies. We suspect that these results reflect the limited capacity of the fertilized ovum to synthesize DNA; hence, when large amounts of plasmids are injected, DNA synthesis becomes rate limiting rather than conversion of I-dC to I-dCMP by viral TK.

To obviate this problem, we determined TK activity directly by measuring the conversion of ³H-labelled thymidine to ³H-TMP by homogenates of ova prepared 22 h after plasmid injection. With this assay, enzyme activity was nearly linear when up to 20,000 copies of plasmid were injected per ovum (Table 1b). Thus, the indirect assay with ¹²⁵I-dC provides sensitivity to small numbers of injected genes while the direct assay with ³H-thymidine is more useful when large numbers of genes are injected.

The results with pMK suggest that the MT-I gene promoter is substituting for the TK gene promoter to allow transcription of a functional TK mRNA. To ascertain whether the 5'-flanking region of the MT-I gene also allows regulation of transcription by heavy metals or glucocorticoids, the injected ova were incubated for 22 h with or without 50 μM Cd or 100 nM dexamethasone before TK assay. Table 2 shows that Cd treatment results in a dramatic increase in TK activity when 200 or 2,000 gene copies were injected per ovum. When 20 gene copies were injected the response to Cd was low; however, when the more sensitive ¹²⁵I-dĈ technique was used, a 2.5-fold increase in TK activity was detected after Cd treatment (data not shown). The amount of TK activity obtained when plasmid pTK was injected was unaffected by Cd treatment (data not shown). These results indicate that the molecules responsible for heavy metal regulation of MT-I gene transcription are present in mouse ova and that the regulatory sequences are contained within the 1.7 kb of mouse DNA 5' of the BglII site. We have not detected any increase in TK activity in response to dexamethasone treatment using either assay. This may be due to the absence of functional glucocorticoid receptors, lack of necessary DNA sequences, or inappropriate chromatin structure.

We attempted to eliminate gene activity by cutting the pMK plasmid between the MT-I promoter and the TK structural gene at the BglII site (see Fig. 1). Some of the linearized molecules were treated with DNA polymerase I (Klenow fragment) to fill in the 'sticky ends' generated by BglII. In both cases the linearized molecules were separated from any uncut molecules or nicked circles by agarose gel electrophoresis. Table 3 shows that despite the separation of MT-I promoter from the TK structural gene, the injected ova still produced a high level of TK activity, whether or not the DNA ends were blunted with DNA polymerase I. Furthermore, the TK activity was greatly enhanced by Cd treatment. A likely explanation for these results is that the mouse ovum has the requisite enzymes necessary to re-ligate the linearized pMK plasmid. Comparison of the TK activity generated with different dosages of plasmids indicates that the activity obtained with the blunt-ended fragment is essentially the same as with supercoiled plasmid (compare Tables 2 and 3), suggesting that re-ligation is very efficient. Analysis of DNA injected into eggs by agarose gel electrophoresis and Southern blotting confirms that linear DNA molecules become re-ligated and supercoiled (data not shown).

To examine this phenomenon further, the pMK plasmid was cut to yield individual 'regulatory region' (PsI to BglII) and 'structural gene' (BglII to PvuII) fragments (see Fig. 1, inner circle). Each fragment was injected separately and in combination, as shown in Table 3. When high levels (4,000 per nucleus) of the separate fragments were injected no significant increase in TK activity above control levels was observed. Furthermore, injection of 4,000 molecules of both fragments did not result in demonstrable TK activity. However, re-ligation of the fragments in vitro followed by injection resulted in high levels of TK activity which were further elevated by Cd treatment. Injection of higher levels (24,000 molecules) of the separate fragments was also effective. Our interpretation of these results is that the

individual 'regulatory region' and 'structural gene' sequences do not have TK activity and that correct ligation of the separate fragments is inefficient compared with the circularization of the linearized plasmid.

Deletion mutants define promoter and regulatory sites

To define more precisely the mouse DNA sequences required for cadmium regulation we prepared a set of deletion mutants. The first step entailed deletion of a 3.0-kb PvuII fragment including the 3'-flanking region of the TK gene and nonessential pBR322 sequences; this fragment includes an EcoRI site that complicates construction of subsequent deletions. A set of deletions extending from the remaining EcoRI site towards the TK gene was then prepared by restriction with specific enzymes and re-ligation of blunted ends, as indicated in Fig. 1. To extend further towards the TK gene from the SstI site, the double-strand exonuclease Bal31, was used and an EcoRI linker inserted to facilitate mapping. The approximate (± 5 base pairs [bp]) end points of these deletions are indicated by arrows on the sequence at the bottom of Fig. 1. Figure 1 (histograms) shows that there was a progressive loss of constitutive as well as Cd-induced activity as the 5' sequences were deleted. TK activity measured in the absence of Cd was more severely decreased than in its presence; thus the ratio of activity with and without Cd increased (as indicated by the numbers over the histograms) until the minimal sequence required for Cd regulation was reached. The minimal sequence tested that preserves Cd regulation (\Delta ES_{60}) retains ~90 nucleotides of mouse DNA 5' of the transcription start site and includes a large palindrome centred at position -55. Deletions that extend into this palindrome (ΔES_{100}) or delete all the mouse sequences (ΔEBg) have no activity (<1.5 times background) and are not inducible by Cd. These data indicate that the 5' MT-I sequence carries both promoter and Cd regulatory sites. Although a minimal sequence can be described (exemplified by ΔES_{60}), additional sequences that potentiate both basal and induced activities clearly extend at least to the KpnI site, which is ~ 600 bp 5' of the transcription start site.

We conclude that fusion of the MT-I and HSV TK genes at their respective BglII sites results in a gene that is transcribed, presumably by RNA polymerase II4, and that the mRNA is translated into functional TK. Furthermore, the gene fusion is regulated by Cd in a manner similar to the endogenous MT-I gene. We have as yet been unable to dissociate a functional promoter from cadmium regulation. By 5'-deletion analysis we have identified a minimal control region that includes ~90 nucleotides 5' of the transcription start site. Plasmids that contain only 50 nucleotides 5' of the transcription start site are inactive plus or minus cadmium, despite the fact that they retain the TATAAA sequence that is generally required for transcription in vitro. These boundaries lie close to those defined by

Table 2 Cd regulation of the amount of TK activity produced from pMK

	Formation of ³ H-TM	MP (c.p.m.×10 ⁻³)*
No. of pMK plasmids injected	Ova cultured without Cd	Ova cultured in 50 µM Cd
2,000	190.0	2,400
200	25.3	270
20	8.3	12.2
0	8.5	8.8

Ova were injected with the number of pMK plasmids indicated as described in Table 1 legend. The ova were then randomly divided into two groups and incubated for 22 h with either 0 or 50 µM Cd in the medium. TK activity was measured as described in Table 1 legend.

* Each value is the mean of ³H-TMP formed by 25 ova in two separate experiments.

Table 3 TK activity of restriction fragments derived from pMK

Plasmid treatment*	No. of DNA molecules injected		n of ³ H-TMP .×10 ⁻³)† +50 μM Cd
PMK restricted with BglII	2,000	92.6	1,000
pMK restricted with Bg/II	2,000	68.3	1,480
and blunt-ended with DNA	400	50 8	514
polymerase I	80	5.1	39.9
TK 'structural gene' fragment (BglII to PvuII)	4,000	6.8	6.5
MT-I 'regulatory region' fragment (PxI to Bg/II)	4,000	7 8	11.4
TK 'structural gene' and MT-I 'regulatory region' re-ligated in vitro	4,000 of each	105	407
TK 'structural gene' and MT-I	4,000 of each	11.9	10.1
'regulatory region' injected as separate fragments	24,000 of each	139	595
No plasmid injected	0	8.4	7.9

* Plasmid pMK was restricted with Bg/II; one-half of the sample was incubated with DNA polymerase I (Klenow fragment) in the presence of all four deoxyribonucleotide triphosphates. Then the DNA was electrophoresed on a 0.7% agarose gel; the linear band was localized by ethidium bromide staining (no supercoils or nicked circles were visible) and the DNA was eluted from the gel by the NaClO₄ method³² The TK 'structural gene' and MT-I 'regulatory region' fragments were stolated by cutting pMK with PstI, Bg/II and PvuII and separating the fragments on a 1% agarose gel and eluting them as described above. For re-ligation in vitro, 1.2 µg of the PstI-BglII fragment (2,500 bp) was mixed with 0 9 μg of the Bg/II-PvuII fragment (1,700 bp) in a 50 μl reaction mixture with T4 ligase and incubated for 6 h at 15 °C After ligation the mixture was extracted with SDS, phenol and chloroform, and the DNA was precipitated with ethanol.

† Ova were injected with the indicated number of DNA molecules and incubated for 22 h with (+) or without (-) 50 μ M Cd before TK assay as described

in Table 1 legend.

McKnight et al. 15 for the TK promoter. However, in contrast to their results, we find that sequences further upstream of -90 potentiate transcription. Some of these sequences allow transcription in the absence of Cd and may, therefore, represent additional promoters. Similar potentiating effects of upstream DNA sequences have been described for histone genes¹². The nature of the molecules involved in heavy metal regulation of MT-I genes is unknown, but they are apparently ubiquitous because we have demonstrated heavy metal regulation of MT-I genes in a wide variety of mouse organs², cell culture lines³ and now mouse oocytes and eggs. This feature may be useful for constructing expression vectors that can function in a wide variety of cell types. Another possibility we are exploring is that this regulatable gene can be introduced into mice by injecting plasmids into fertilized eggs and then implanting the eggs into pseudopregnant mice. The basic feasibility of this approach has been demonstrated²³ and preliminary results indicate that this fusion gene is indeed regulated in mouse liver.

We thank Myrna Trumbauer for assistance, Steven McKnight for sending us a preprint of his manuscript, and S. Kit and A. Senear for helpful comments and suggestions. Financial support was from NIH grant HD 12384 and NSF grant PCM 78-22931 to R.L.B. and NIH grant HD 09172 to R.D.P. H.Y.C. was a trainee on HD 00239.

Association of PSR0740-28 with an H I shell in Puppis

J. Gregory Stacy

Astronomy Program, University of Maryland, College Park, Maryland 20742, USA

P. D. Jackson

Department of Physics, York University, Downsview, Ontario, Canada M3J 1P3

During a survey of the interstellar atomic hydrogen (H I) distribution in the Puppis region of the Milky Way, we detected numerous, sometimes expanding, HI shells and filaments, indicative of past energetic explosive events in this area of the Galaxy. One of these shells, GS241-01+15, appears to be physically associated with the young pulsar PSR0740-28. In particular, the pulsar is coincident in position with an HI hotspot on the rim of the shell, and there are two nearby non-thermal radio sources, one of which lies on the rim of the H I shell coincident with the position of the open cluster Hf11, the other lying near the centre of the shell. Both non-thermal sources have been previously identified as possible supernova remnants (SNRs)^{1,1}. Furthermore, velocity measurements of the peak emission from the hydrogen shell and of the 21-cm absorption spectrum of the pulsar offer strong confirmation that the pulsar and the HI shell lie at the same distance from the Sun. This result is of interest because very few pulsars have been linked to known supernova remnants, and only the Crab and Vela pulsars with any degree of certainty3. Whether the pulsar PSR0740-28 is the remnant of the supernova progenitor of the HI ring, or perhaps the remnant of an early supernova in a young stellar group which was formed by the expanding HI shell, is as yet unclear. Present data seem to support the latter interpretation, suggesting that PSR0740-28 may have resulted from a 'second-generation' supernova event.

The correlation between pulsar and shell positions was noted during an analysis of a 21-cm neutral hydrogen survey of a region of the galactic disk known as the Puppis window. This unique area of the Milky Way contains much less absorbing interstellar dust and associated gas than is found in more typical regions of the Galaxy. In fact, galaxies have been observed near the galactic equator^{4,5}. It is estimated that the total visual extinction out to the edge of the galactic disk in the direction of galactic longitude $l = 245^{\circ}$ is only four to five magnitudes⁴. This is a favourable longitude for study of large-scale galactic kinematics as it is near the middle of the third quadrant of galactic longitude where circular galactic rotation provides a near optimum ratio of radial velocity to distance. Hence, this region of the Galaxy is ideally suited for the comparison of optical and radio observations, extending out to much greater

distances than is normally feasible in other portions of the galactic disk. In addition, large holes and gaps in the HI gas distribution, in velocity space, make this region particularly suitable for the identification of shells and ring-like structures, as a lack of foreground and background gas along various lines-of-sight minimizes the confusion of sources which would otherwise result.

The radio observations were conducted on the 43-m National Radio Astronomy Observatory (NRAO) radio telescope at Green Bank, West Virginia during two observing sessions: 22-28 June 1979 and 12-19 May 1980. The area observed consists of a 61×61 grid of points in the sky, extending from galactic longitudes $l = 239^{\circ}$ to 251° and from galactic latitudes $b = -9^{\circ}$ to $+3^{\circ}$, every 0.2° in l and b. The half-power beamwidth of the telescope at the 21-cm wavelength corresponding to neutral hydrogen emission is 21 arc min. The main results of our survey, along with a detailed description of our data reduction procedure, will be presented elsewhere⁶.

The H I shell which we denote by GS241-01+15 (GS refers to galactic shell, followed by position and velocity information in the format $l + b + v_{LSR}$, where all velocities have been referred to the local standard of rest (LSR)) was previously noted by Heiles⁷ in his analysis of the Berkeley low-latitude survey of neutral hydrogen⁸, and labelled as GS242-01+11. The finer spatial and velocity resolution of the present survey accounts for the differences in position and velocity range reported for this object. The centre of this HI shell coincides with an extended (1.2°×1.2°) radio source G240.8-1.2 discovered in a 29.9-MHz continuum survey by Jones and Finlay, and tentatively identified as a SNR1. The more recent 408 MHz maps of Haslam et al.9 contain a hint of this ring-like HI feature, though the correlation is far from exact.

The pulsar position ($l = 243.8^{\circ}$, $b = -2.4^{\circ}$) places it on the eastern edge of the HI shell, coincident with a fairly strong peak of 21-cm emission (HI cloud GC244-03+15) and just adjacent to another extended $(1^{\circ} \times 1^{\circ})$ non-thermal radio source G242.5-3.5 (see Figs 1 and 2)¹. Gomez-Gonzalez *et al.*¹⁰ detected strong absorption towards the pulsar in their observations with the Nançay radio telescope, having a velocity resolution of 12.7 km s⁻¹. Half of the pulsar signal is absorbed in their channel centred at +19.5 km s⁻¹, indicating that the absorption extends to at least the centre velocity. No absorption at all is seen in the next channel, centred at +32.2 km s⁻¹, indicating that the absorption has stopped before the lower velocity range of this channel, at ~+26 km s⁻¹. Thus absorption ceases between +19.5 and +26 km s⁻¹. The highest velocity at which we can still recognize the shell GS241-01+15 in emission is at about $+20~\rm km~s^{-1}$ where it blends in with strong generalized emission. This general emission peaks near $+20 \,\mathrm{km} \,\mathrm{s}^{-1}$ but extends to about $+30 \,\mathrm{km} \,\mathrm{s}^{-1}$ (see ref. 8). Since HI clouds which absorb the pulsar's signals must lie closer to us than the pulsar and HI clouds which do not appear in absorption presumably lie beyond the pulsar, the observed absorption indicates that the pulsar is at least as distant as the shell, and yet is not as distant as the numerous clouds causing the widespread HI emission at slightly higher velocities (and which are presumably lying just beyond the shell). As discussed

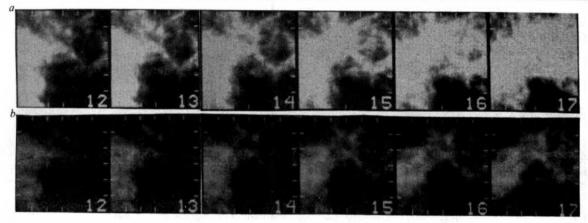

Fig. 1 Synthetic photographs of the constant-velocity neutral hydrogen (H I) distribution in the vicinity of the H I shell GS241-01+15 over the LSR velocity range +12 to +17 km s⁻¹. Tick marks are included in each map at 2° intervals at odd values of galactic longitude and latitude. Each map extends from $l = 239^{\circ}$ to 251° (right-to-left) and from $b = +3^{\circ}$ to -9° (top-to-bottom). a, Highlights H I brightness temperatures over the range 5-50 K; b, over the range 25-105 K. The pulsar PSR0740-28 lies on the hotspot ($l = 243.6^{\circ}$, $b = -2.6^{\circ}$) on the lower left rim of the shell.

by Weisberg et al.¹¹, bright H I emission clouds in the Milky Way rarely fail to provide significant absorption against extragalactic radio sources. Thus the pulsar PSR0740-28 lies not only on a hotspot of the H I shell in position, but also coincides with it in distance. The most recent distance estimate to this object, derived from a combination of dispersion measurements and H I absorption observations, is listed as 1.5 kpc (ref. 12), very nearly equivalent to our estimated kinematic distance of 1.4 kpc to the H I shell. We now consider possible physical mechanisms connecting the pulsar and the shell.

A summary of the observed and derived parameters describing the pulsar PSR0740-28, the H I shell GS241-01+15 and the H I cloud GC244-03+15 is given in Table 1.

PSR0740 – 28 is a very short-period pulsar (currently eighth-ranking of 330 pulsars by pulse period), whose measured period derivative implies a characteristic age of 1.58×10^5 yr (refs 12, 13). Striking similarities between PSR0740 – 28 and the Vela pulsar in terms of pulse shape and polarization properties have been noted ¹⁴. At the time of its discovery ¹⁵, it was noted that the pulsar PSR0740 – 28 was among the youngest detected without apparent association to a known SNR ¹⁵.

To determine more precisely the relationship of the H I shell GS241-01+15 to the pulsar PSR0740-28, it is of interest to estimate the age of this presumed SNR for comparison. Unfortunately, most models $^{16.17}$ relating the linear diameter of a SNR to its age are of questionable applicability in the present case as their results are appropriate for relatively young SNRs in the Sedov adiabatic expansion phase of their development. Our shell GS241-01+15, however, exhibits no appreciable variation in angular size with velocity, implying minimal expansion. This fact, coupled with the large linear size of the shell (~ 170 pc), leads us to believe that, if anything, GS241-01+15 is in transition from the isothermal expansion phase of its existence to the extinction phase, when the SNR begins to lose its identity as it merges with the interstellar medium.

Substituting typical values for initial supernova energy and ambient interstellar density into equation (1) of Herbst and Assousa¹⁸ yields an age in the range 10⁶-10⁷ yr for the shell GS241-01+15. Although the assumption of an unusually large supernova energy might bring the pulsar and shell ages into closer agreement, the indication is that such a large diameter H I shell has an age greater than that of PSR0740-28. Nonetheless, even disregarding the large uncertainties inherent in these estimates, such discrepancies between pulsar and SNR ages in reported associations (up to two orders of magnitude in some cases^{2,19}) have been said to have important implications in such fundamental areas as "supernova collapse theory, pulsar

acceleration mechanisms, and the birth rate and evolution of the galactic pulsar population".19.

Another factor to be considered is the displacement of the pulsar from the centre of the H I shell. Taking an angular separation between the pulsar and shell centre of $\sim 3.1^{\circ}$, and a distance of ~ 1.4 kpc, one finds that the pulsar is linearly displaced by about 75 pc from the centre of the H I ring. Assuming that the pulsar was originally at the centre of the H I shell, one may calculate its average annual proper motion, over a presumed lifetime of 1.58×10^{5} yr. This value is found to be ~ 70 m arc s yr⁻¹, corresponding to a space velocity of ~ 500 km s⁻¹. Though large (even for such notorious high-velocity objects as pulsars), at least two pulsars have been

Column headings for the HI shell and cloud are: lctr, bctr, galactic longitude and latitude of the centre of the radio features; Δl , Δb , approximate angular extent of the radio features in l and b (estimated to the nearest quarter degree); V_{min} , V_{max} , minimum and maximum LSR radial velocities between which the HI features are detected; Δr , the angular radial thickness of the HI shell (estimated to the nearest quarter degree); d, distance to the features from the Sun, calculated by applying a flat galactic rotation curve and using the LSR velocity of peak emission; LD, linear diameter of the H I features; $N_{\rm H I}$, H I column density within the shell or cloud (cm⁻²); n, particle number density within the shell or cloud (cm⁻²), assuming 10% helium abundance by number; M, total mass contained within the shell or cloud expressed in solar masses, assuming 10% helium abundance by number. Pulsar column headings: l, b, galactic longitude and latitude; P, pulse period; P, period derivative; HI absorp., LSR velocity of HI absorption; d, distance from the Sun; Age, characteristic age. All pulsar parameters are from ref. 12 except column 5 which is from ref. 10.

observed with transverse velocities in excess of 500 km s⁻¹ (refs 20, 21), and pulsar velocities up to several thousand km s⁻¹ have been repeatedly invoked to explain previously reported pulsar-SNR associations^{2,19}.

An alternate hypothesis regarding the origin of the pulsar is that the supernova which gave birth to PSR0740-28 was not the same one as that which gave rise to the HI shell. In other words, the pulsar has resulted from a relatively recent supernova event in a very young stellar group which was formed by the gradual expansion of the much older H i shell into an adjacent HI cloud, with subsequent shock-wave induced star formation. The presence of the pulsar in a hot spot on the HI shell, just adjacent to a non-thermal radio source, supports this interpretation. No obvious evidence of this second later supernova should be expected in our current HI observations, as the expected size of such a distant and young H I shell would be comparable to the beam size of the 43-m NRAO antenna. Such a second hypothesis supports the results of Morris et al.2 in naming the non-thermal source G242.5-3.5 as the likely point-of-origin of PSR0740-28, while simultaneously explaining its proximity to the non-thermal source G240.8-1.2 and the extended H I shell GS241-01+15, remnants of a much earlier supernova.

The position angle of PSR0740 -28 relative to G242.5 -3.5is 110°, and relative to G240.8-1.2 is 173°. According to Morris et al.², the intrinsic polarization vector for PSR0740 -28lies at 108°±4°, and the former source is the preferred point of origin for the pulsar, as it places the quantity (polarization angle minus position vector) close to the secondary peak (at 0°) in the probability distribution of this quantity as plotted for several pulsars. The angular separation between PSR0740-28 and G242.5 – 3.5 (\sim 1.7°) also implies a more reasonable transverse velocity of \sim 250 km s⁻¹. A logical follow-up to this hypothesis would be proper motion studies of PSR0740-28. The proper motions mentioned above should be detectable, and offer the means of differentiating between the H I shell and G242.5-3.5 as the more likely origin of the pulsar. Note how cloud GC244-03+15 is apparently elongated along the line joining the pulsar to G242.5-3.5. The position of G242.5-3.5also falls within the boundaries of the compact open cluster OCl-657 = Hf11 $(l = 242.41^{\circ}, b = -3.56^{\circ})^{22}$. Other open clusters which have been associated with SNRs are Tr18 (ref. 23) and NGC559 (ref. 24). Very little is currently known about Hf11, which is also listed as cluster number 3 in the compilation of van den Bergh and Hagen²⁵, and thus we cannot determine whether its age is consistent with the age of the HI shell. Clearly, a programme of photometry and spectroscopy on this cluster is necessary to determine its age.

Other clusters in the general vicinity which may be related to the H I shell GS241 – 01 + 15 are Tr9 ($l = 243.1^{\circ}$, $b = +1.2^{\circ}$) and NGC2453 ($l = 243.3^{\circ}$, $b = -0.9^{\circ}$). Fenkart and Binggeli²⁶ give distances and earliest spectral types of 2.23 kpc and b5 for

Tr9, and 1.49 kpc and b7 for NGC2453. A search for very young stars and molecular clouds in the vicinity of the pulsar and near other H I hotspots on the shell might provide further evidence for possible shock-wave induced star formation along the eastern rim of the HI shell (thus supporting the latter hypothesis of origin of the pulsar).

The coincidence in both coordinate position and distance of the pulsar PSR0740-28 and the neutral hydrogen shell GS241-01+15, in conjunction with the presence of two nearby non-thermal radio sources, G242.5-3.5 and G240.8-1.2, is strong support for the physical relationship of these two objects. It is not yet clear whether the pulsar and the H I shell originated in a single supernova event, or whether formation of the HI shell may have preceded the birth of PSR0740-28. The current data seem to indicate that PSR0740-28 may be the remnant of a second-generation supernova, in support of the conclusions of Morris et al.2 regarding the relationship between the pulsar and the non-thermal source G242.5-3.5. Future observations, particularly proper motion studies, should clarify the situation.

We thank A.S. Wilson for useful discussions and D. Klinglesmith for arranging use of the Interactive Astronomical Data Analysis Facility of the Goddard Space Flight Center. Partial support of this research was provided by the NSF through grant AST 80-21283 to Professor F. J. Kerr of the University of Maryland. The National Radio Astronomy Observatory is operated by Associated Universities, Inc., under contract with NSF.

Overshoots in planetary bow shocks

C. T. Russell, M. M. Hoppe & W. A. Livesey

Institute of Geophysics and Planetary Physics, University of California, Los Angeles, California 90024, USA

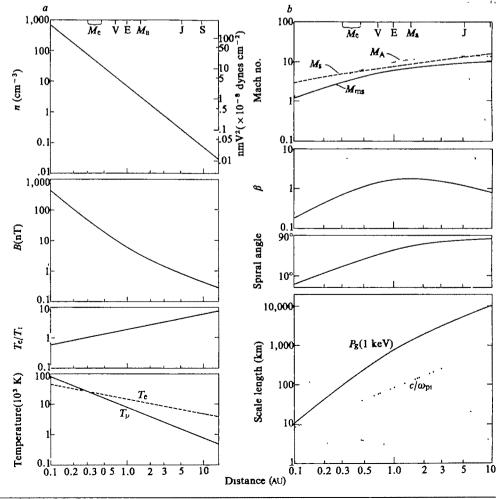

An overshoot in the magnitude of the magnetic field is shown here to be a consistent feature of supercritical collisionless shocks, Mach number ≥3, throughout the Solar System. Although the variability of the solar wind at 1 AU allows us to study the Earth's bow shock over a wide range of B, the ratio of thermal pressure to magnetic pressure, the Mach number of the solar wind at 1 AU varies over a relatively narrow range. Data from Jupiter and Saturn allow us to study the bow shock at high Mach numbers rarely, if ever, observed at Earth. These combined planetary data show that the planetary bow shocks, at least as characterized by their overshoots, form part of a continuum, differences being dependent mainly on the varying solar wind conditions at each of the planets. The overshoot magnitude is found to increase both with β and magnetosonic Mach number. However, it is the radial variation of Mach number which causes the overshoot in the jovian and saturnian bow shocks to be much greater than in the terrestrial shock.

Collisionless bow shock waves exist in front of each planet probed by planetary spacecraft so far. These shocks both deflect the supersonic, or supermagnetosonic, solar wind around the planets and heat the solar wind. Part of the incoming solar wind is accelerated or 'reflected' by the shock back along magnetic field lines towards the Sun. This reflection process has been described geometrically by Sonnerup¹ but no detailed mechanism has yet been postulated to reflect the observed small fraction of the incoming ion beam. The change in the solar wind

plasma across the bow shock can be understood in magnetohydrodynamic formalism according to the Rankine-Hugoniot equations². However, these equations do not describe the plasma physical processes by which the heating and deflection occur, the relative energization of ions and electrons, the heat flux represented by the 'reflected' ion beams, or the fine scale structure of the shock on scale lengths comparable to an ion gyro-radius or less. Investigation of the microphysics of collisionless shocks is necessary to understand these processes and to learn why in collisionless shocks a small fraction of the particles receives a large fraction of the energy. This behaviour is important, not just for understanding the creation of energetic particles in the Solar System, but also for understanding the generation cosmic rays outside the Solar System. It is quite likely that stellar, interstellar and even intergalactic shocks are producing cosmic ray beams analogous to the ion beams in planetary foreshocks.

Because of the dispersive nature of waves in a plasma one would expect damped wave trains either upstream or downstream from the shock front². What is generally observed in planetary shocks is a single approximately critically damped wave cycle or overshoot in the magnetic field strength. This overshoot was first noted by Heppner et al.³ in OGO 1 magnetic field records and later reported in ISEE 1 and 2 data^{4,5}, in which it was shown that while electron acceleration is coincident with the overshoot in field magnitude, ion thermalization is not complete until the overshoot has finished and the field returns approximately to its equilibrium or Rankine-Hugoniot value. There is reason to believe this overshoot is associated intimately with the ion 'reflection' process for unpublished ISEE magnetic field data indicate a scale length for the overshoot comparable to the ion gyro-radius, and the plasma data show ions reflected by the overshoot. These observations are supported by computer simulations which also demonstrate the ion gyration nature of the overshoot6.

1 Typical solar parameters as a function of heliocentric distance. a, Number density and dynamic pressure (top panel), magnetic field strength, ratio of electron to proton temperature, and the electron and proton temperatures. b, Mach numbers, Alfvén, sonic and magnetosonic (top panel), β (ratio of thermal to magnetic pressure), the spiral angle (angle between interplanetary field and solar wind flow) gyroradius of 1-kev proton and the ion inertial length. The labels at the top give the planetary positions.

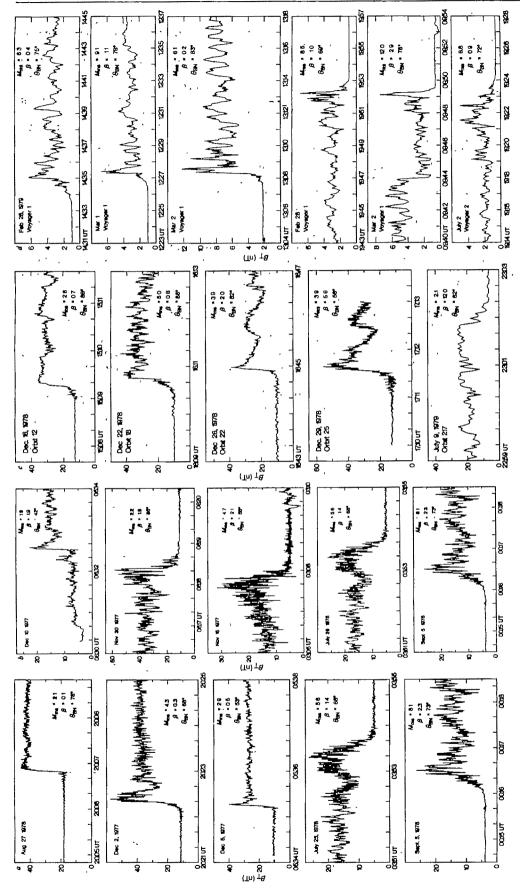

Fig. 2 Magnetic field profiles of the terrestrial bow shock as observed by the ISEE 1 magnetometer in a variety of solar wind conditions. a, β increases from top to bottom. b, Magnetosonic Mach number increases from top to bottom. c, Magnetic field profiles of the Venus bow shock in a variety of solar wind conditions. The top two panels contrast shocks for different Mach number. The middle two panels contrast shocks for differing β , d, Six crossings of the joynan bow shock as detected by Voyagers 1 and 2.

Although the existence of the overshoot in the terrestrial shock has long been known, its parametric variation with solar wind conditions has not been studied nor has its possible importance in the ion reflection mechanism been appreciated. We now consider the parametric variation of the overshoot with solar wind conditions by using both terrestrial and planetary

bow shock data. At the Earth the day-to-day variability of the solar wind and variation of the angle between the solar wind flow and magnetic field and the shock normal along the curved bow shock provide a wide range of plasma conditions. On the other hand, despite this variability the range of plasma conditions at 1 AU is limited and examples of shocks in some interesting

portions of parameter space, especially at high Mach numbers, are rare. This difficulty can be partially overcome through studying the bow shocks of the other planets as the variation of the solar wind properties with heliocentric distance places each of the planets in a different average environment.

This variation is illustrated in Fig. 1a, in which the dependence of various solar wind parameters is plotted as a function of heliocentric distance. The curves were constructed by taking estimates of typical values at the Earth (J. T. Gosling, personal communication), assuming a constant solar wind speed and scaling density as r^{-2} , magnetic field strength as r^{-1} ($r^{-2}+1$)^{1/2}, proton temperature as r^{-1} and electron temperature as $r^{-1/2}$. In addition to these basic parameters we have studied the radial dependence of a set of physical quantities derived from them which have proved useful in classifying shock structure. These quantities are plotted against heliocentric distance in Fig. 1b. Included are plots of β , the spiral angle of the interplanetary field, the length scales of the ion gyroradius $(\rho_{\mathbf{z}})$ and ion inertial length (c/ω_{pl}) and three Mach numbers. The Mach numbers are the Alfvén Mach number, the ratio of the solar wind velocity with respect to the Alfvén velocity, the sonic Mach number, the ratio of the solar wind velocity to the sound velocity and the magnetosonic Mach number, the ratio of the solar wind velocity to the magnetosonic velocity, or fast mode velocity. The magnetosonic velocity is calculated for propagation perpendicular to the magnetic field and is the square root of the sum of the squares of the Alfvén and sound velocities. All of the Mach numbers rise monotonically by factors ~3 from the orbit of Mercury to that of Saturn.

If the magnetosonic velocity were corrected for its dependence on angle of propagation to the magnetic field, the corrections would be small, especially at the larger heliocentric distances where the spiral angle of the interplanetary magnetic field becomes more perpendicular to the solar wind velocity. β first increases and then decreases with increasing distance, rising to its maximum just beyond the orbit of the Earth. The ion inertial length and gyroradius increase by one and two orders of magnitude respectively from Mercury to Saturn.

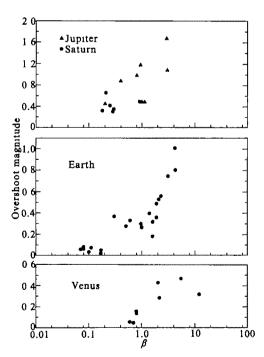

Fig. 3 Strength of the overshoot in the magnetic field immediately behind the shock as a function of β for Venus, Earth, Jupiter and Saturn. The overshoot magnitude is defined to be the maximum field strength minus the equilibrium average field strength some distance behind the shock normalized by this equilibrium average. The scale for the upper panel is double that of the bottom two panels.

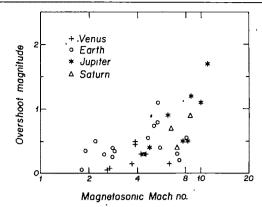

Fig. 4 The magnitude of the overshoot as a function of magnetosonic Mach number.

Experimental evidence that these predicted changes in plasma environment from planet to planet are reflected in the evolution of bow shock structure with heliocentric distance has been provided by Scarf et al.⁷ in their studies of the plasma wave spectra associated with various planetary bow shocks. The very low frequency spectrum across the bow shock of Saturn is distinctly peaked, whereas at Venus it decreases monotonically with increasing frequency. Data at the Earth and Jupiter show intermediate behaviour. Scarf et al.⁷ hypothesize that the nature of the bow shock undergoes a transition in the neighbourhood of a Mach number of 7–10.

We use magnetic field data obtained at Venus, Earth, Jupiter and Saturn to study the heliocentric evolution of bow shock overshoot and its dependence on solar wind parameters. We do not use data obtained at Mercury or Mars because of the paucity and/or unavailability of high resolution data. Figure 2a shows samples of ISEE 1 magnetic profiles across the terrestrial bow shock in a variety of solar wind conditions (Los Alamos Space Plasma Group, personal communication). On 27 August 1978 at low Mach number and β there is little if any post-shock overshoot in the magnetic field. However, at higher Mach number and β the overshoot is quite prominent. These shocks have been arranged in order of increasing β from top to bottom.

There is a variety of shock structure; the field can at times be quite irregular and the overshoot can be difficult to define unambiguously or to distinguish from 'normal' magnetosheath fluctuations. We have chosen a simple empirical parameterization of the overshoot and define the magnitude of the overshoot to be the difference between the equilibrium or average downstream field strength and the maximum field strength just behind the shock normalized by the equilibrium average field strength.

Figure 2b shows a set of shocks similar to those in Fig 2a arranged in order of increasing magnetosonic Mach number with β held fixed at \sim 2. There seems to be an evolution in structure with changing Mach number but the evolution is partly masked by our inability to fix the angle between the upstream field and the shock normal. Furthermore, despite our examination of >1 yr of ISEE data we have been unable to separate clearly Mach number effects from β effects. Indeed the bottom two examples in Fig. 2a, b are the same cases.

Similar sets of shocks with contrasting solar wind parameters chosen from Pioneer Venus Orbiter data⁹ are shown in Fig. 2c. Solar wind conditions at Venus are similar to those seen at Earth, and the bow shock structure is similar although weaker than the terrestrial shock¹⁰. The top two panels of Fig. 2c contrast the bow shock at fixed β and angle between the magnetic field and shock normal but with different Mach number. The second pair show the increase in turbulence associated with an increase in β . The bottom panel shows the case with a very high β . However, the low data rate at this time obscures the detailed structure of the shock.

At Jupiter and Saturn we expect lower β than at 1 AU but higher Mach numbers. This is confirmed in Fig. 2d which shows six jovian bow shocks obtained in only a few days as observed by

the GSFC Voyager magnetometer and their associated plasma parameters. The plasma data necessary for the calculation of Mach number and β were provided by the MIT plasma group. It is evident that the jovian overshoots are much bigger than their terrestrial counterparts. Data for the bow shock of Saturn have recently been published11 and will not be repeated here. The Mach number during the Pioneer 11 passage by Saturn was less than at Jupiter during the Voyager encounters. However, it was still much greater than normally observed at 1 AU.

The two parameters which seem to control the structure of the shock in Fig. 2 are β and Mach number. Thus we have taken a sample of the bow shocks at Venus, Earth, Jupiter and Saturn including those shown and examined the overshoot as a function of β and Mach number. Figure 3 shows the amplitude of these overshoots plotted against β for Venus and the Earth separately and Jupiter and Saturn combined. The scale for Jupiter and Saturn is twice that for Venus and Earth so that there is a different variation at the outer planets. However, qualitatively there is a clear trend of increasing overshoot with increasing β for all the planets.

Figure 4 indicates that the difference between the overshoots at the various planets is due to the difference in Mach number.

Plotting all the planetary data as a function of magnetosonic Mach number suggests that the trends for each planet coincide. The principal difference being the range of Mach numbers at each planet. Clearly there is also a dependence on β , but the range of B is similar at each planet. We have also checked to see whether the apparent β and Mach number dependences could have been caused by a correlation between β and Mach number but there is, in fact, little correlation between these two parameters, except in the terrestrial data set by itself in which high Mach numbers were always accompanied by high betas.

We conclude that the bow shock structure, notably the magnitude of the overshoot in field strength post-shock, depends on both β and magnetosonic Mach number. This dependence seems to be continuous and we find no evidence for a sudden change in structure at the highest Mach numbers at least as observed in the magnitude of the magnetic overshoot.

We thank S. J. Bame, A. Barnes, H. Bridge, J. T. Gosling, A. J. Lazarus and J. Scudder for the plasma data. The Voyager magnetic field (N. Ness, P.I.) were provided by the National Space Science Data Center. This research was supported by NASA under contracts NAS2-9491 and NAS5-25772 and under grants NGL 5-007-190 and NAGW 162.

Magnetoid interaction with surrounding stars

L. M. Ozernoy* & V. V. Usov†

* Department of Theoretical Physics, Lebedev Physical Institute, Academy of Sciences of USSR. Moscow 117924, USSR

† Space Research Institute, Academy of Sciences of USSR, Moscow 117810, USSR

Lugg¹ has recently analysed a magnetoid—a supermassive rotating highly magnetized star²⁻⁵—situated at the centre of a compact galactic nucleus in the belief that previous investigations had taken no account of interaction with neighbouring stars. Such an interaction has been widely discussed⁶⁻¹¹, but there has been no confirmation of the main conclusion of ref. 1 that these stars can disrupt a magnetoid in as short a time as 104 yr. Here we demonstrate that this conclusion is erroneous.

On penetrating a magnetoid, stars greatly decelerate and thus, in gradually losing their kinetic energy, settle to the magnetoid's centre. Although this process is accompanied by numerous complex phenomena (such as shock-wave generation, ablation, interaction of radiation with star atmospheres and partial mass loss by stars) we shall assume, as in ref. 1, that a supermassive star (superstar) supported mainly by radiation pressure will be formed eventually from the captured stars at the magnetoid's centre. Lugg believes that such a superstar will collapse as soon as its mass exceeds $10^5 M_{\odot}$. However, this value for the critical mass used in ref. 1 has been taken from the theory for an isolated superstar whereas in the present case the central superstar is under an appreciable external pressure. We shall show now that in these conditions the critical mass can be much greater than $10^{\circ} M_{\odot}$.

In the first post-newtonian approximation, the equilibrium energy of a superstar with mass M and radius R experiencing an external pressure $P_{\bullet}(R)$ on its surface, takes the form

$$\mathscr{E}_{\bullet} = -(3\gamma - 4)E_{\text{th}} + 4\pi R^{3}P_{\bullet} + \int 4\pi r^{2}P_{\bullet}(r) dr + \zeta_{1} \frac{G^{2}M^{3}}{R^{2}c^{2}}$$
 (1)

where $(3\gamma - 4) = \beta/2$, $\beta = (gas pressure/total pressure) =$

4.3 $\mu^{-1}(M/M_{\odot})^{-1/2}$ where μ is the mean molecular weight per particle. It is convenient to approximate $P_{\mathbf{s}}(R) \sim R^{-q}$ with q =constant. Then, considering the superstar as a polytrope of index three $(\zeta_1 = 5.06)$ we have in the critical state $(d\mathcal{E}_o/dR = 0)$:

$$R_{\rm cr} = \frac{6.8}{\beta + 2(4 - q)\alpha} R_{\rm S} \tag{2}$$

 $R_{\rm S} = 2 \, GM/c^2$ being the Schwarzschild radius; $\alpha = P_{\rm s}/\tilde{P} = 94 (M_{\rm m}/M)^2 (R/R_{\rm m})^4$; $M_{\rm m}$ and $R_{\rm m}$ being mass and radius of the magnetoid embracing the superstar. If $M \ll M_m$, then $q \approx 0$ in a good approximation, so that

$$\frac{R_{cr}}{R_{s}} = \begin{cases} 1.58 \ \mu (M/M_{\odot})^{1/2} & \text{at } \beta \gg 8\alpha \\ 0.85\alpha|_{R=R_{cr}}^{-1} & \text{at } \beta \ll 8\alpha \end{cases}$$
(3)

On comparing the upper line in equation (3) (external pressure is negligibly small) with the lower line (external pressure is substantial) it is clear that in the latter case the value of the critical mass, M_{cr} , is much greater. We calculate it in a specific case when the superstar is embedded in a magnetoid of mass case when the superstar is embedded in a magnetoid of mass $M_{\rm m}=10^8 M_{\odot}$ and radius $R_{\rm m}=10^{16}\,{\rm cm}$ (the same magnetoid parameters are used in ref. 1). In this case we have $\alpha=1.3\times10^5 (M/M_{\odot})^{2/5}$ at $R=R_{\rm cr}$, and the external pressure term is dominating in equation (3) if $M>1.3\times10^5\,\mu^{-10/9}M_{\odot}$. Making R_{cr} equal to the radius, R_{b} , of the superstar which has reached the hydrogen burning state:

$$\frac{R_{\rm b}}{R_{\rm S}} = 6.84 \times 10^5 \left(\frac{M}{M_{\odot}}\right)^{-0.535} \left[XZ(1+X)\right]^{0.069} \tag{4}$$

(ref. 12) we get for the standard population I composition (X = 0.70, Z = 0.03)

$$M_{\rm cr} = 0.67 \times 10^7 M_{\odot} \text{ for } M_{\rm m} = 10^8 M_{\odot}, R_{\rm m} = 10^{16} \text{ cm}$$
 (5)

At this stage, the radius of the superstar of the critical mass $R_b = 1.2 \times 10^2 R_s = 2.4 \times 10^{14} \text{ cm}$, that is $R_b / R_m \sim 2 \times 10^{-2}$. Such a small value of this ratio implies that the simplifying assumption q = 0 used above to derive equation (3) is well satisfied even for masses as large as M_{cr} given by equation (5).

We see that M_{cr} is much greater than the value $10^5 M_{\odot}$ used in ref. 1. In other words, the central superstar accumulated from the remnants of captured stars will reach the hydrogen burning

stage even without noticeable influence of external pressure if its mass $M < 2 \times 10^5 M_{\odot}$ or due to the pressure if $2 \times 10^5 M_{\odot} \le M \le$ $0.7 \times 10^7 M_{\odot}$. But in neither case does this superstar collapse. Moreover, the nuclear burning gives the superstar a main sequence lifetime of as long as $10^6\,\mathrm{yr}$, independent of its mass and with only a weak dependence of its initial heavy element content¹² unless the hydrogen abundance of the captured stars is abnormally low.

Lugg¹ has found that the mass accumulated in the central superstar is $M \ge 10^5 M_{\odot}$, but such a large value is a result of two basic assumptions made in ref. 1. First, it was assumed that the star cluster surrounding a magnetoid has a mass $M_c \ll M_m$. However, there is considerable evidence in favour of an opposite inequality both for active galactic nuclei and for 'quiescent' ones, such as the nucleus of our Galaxy (see below). As a result, the cross-section for interaction of stars with a magnetoid is equal to

$$\sigma = \pi R_{\rm m}^2 (1 + 2GM_{\rm m}/R_{\rm m}v^2) \approx 2\pi R_{\rm m} r_{\rm c} (M_{\rm m}/M_{\rm c})$$

that is it is smaller than the value in ref. 1 by a factor $M_{\rm m}/M_{\rm c}$ ($r_{\rm c}$ is the core radius). Furthermore, the value $M_m = 10^8 M_{\odot}$ used in ref. 1 should be attributed to a magnetoid which has the characteristics of a quasar but not of an active galactic nucleus, and certainly not that of our own Galaxy. From the requirement that the non-thermal luminosity ($\leq 10^{44}-10^{45}$ erg s⁻¹) observed for active galactic nuclei should be less than or equal to the Eddington luminosity of a hot magnetoid it follows that $M_{\rm m} \leq 10^6$ - $10^7 M_{\odot}$ in active nuclei. Meanwhile the collision rate of stars with the magnetoid is $f = \sigma n_c v \sim M_m R_m (r_c/M_c)^{1/2} n_c$, n_c being the number density of stars in the core. Taking into consideration that $R_m \sim M_m$ (ref. 5) we have $f \sim M_m^2$, that is f decreases greatly as M_m diminishes.

A comparatively low value of M_m is expected in active galactic nuclei, making it reasonable for an inequality $M_m \ll M_c$ (opposite to that used in ref. 1) to take place there. This agrees well with the fact that the velocity dispersion of stars in the cores of both M31 and our Galaxy is as low as $v \approx 200 \text{ km s}^{-1}$ being determined by the gravitational field of an extended mass $M_c \sim 10^7 - 10^8 M_{\odot}$, and not by that of a point (magnetoid) mass of value $M_{\rm m} = 10^8 M_{\odot}$ which gives $v \approx 600 \, {\rm km \, s^{-1}}$. Therefore, if the activity of a Seyfert nucleus is conditioned by the central magnetoid acting within a normal stellar core, inequality $M_{\rm m}$ \ll M_c will be satisfied there. This inequality will only be stronger if the Seyfert phenomenon originates in a galaxy having a more powerful spherical component. (Note that there is strong evidence for such an inequality within the framework of black hole models: see refs 13, 14).

The lower value of M_m and inequality $M_m \ll M_c$ in active nuclei both suggest that the total mass of stars which succeed in sticking inside the magnetoid in the time of refilling of low angular momentum orbits should be considerably less than the value $\ge 10^5 M_{\odot}$ of ref. 1. Even if this mass were much greater (for example, because of collective gravitational effects) but less than M_{cr} given above, it would lead not to its collapse but to a rather slow evolution on the nuclear time scale of about 106 yrcomparable with the lifetime of an isolated magnetoid. Therefore, the conclusion in ref. 1 about the rapid disruption of a magnetoid by the surrounding stars is wrong.

Nevertheless, interaction of stars with the magnetoid has several important and interesting aspects (especially from an observational point of view) mentioned in refs 6-11. Note that we do not regard a magnetoid as the only possible 'engine' responsible for the activity of quasars and nuclei of galaxies. The advantages and difficulties of three possible sources of activitya massive black hole, a magnetoid and compact star cluster-are discussed in detail elsewhere 15-18. The observational tests proposed in refs 15-18 would help to create a realistic theory of the engine.

Initial microbiological response in lakes to the Mt St Helens eruption

John A. Baross*, Clifford N. Dahm†, Amelia K. Ward‡, Marvin D. Lilley* & James R. Sedell§

No published reports exist on the early stages in the establishment and succession of microbial communities and associated chemical and geochemical transformations in aquatic environments shortly after a volcanic event. Much of our understanding of volcanic lakes has come from studies carried out years to centuries after the eruption, when the lakes were already stabilized. Here we document the chemical and microbiological responses of lakes and hydrothermal environments in the blast zone near Mt St Helens 3-4 months after the eruption of 18 May 1980. Within weeks of the eruption, the impacted lakes became anaerobic, ultraeutrophic and developed extensive populations of bacteria, some of which were not common to those environments. By August 1980 both assimilative and dissimilative nitrogen cycle reactions were regulating the extent of chemosynthetic, photosynthetic and heterotrophic activities occurring in the lakes. Recovery of the lakes to their normal oligotrophic state will result in part from oxygen production by photosynthesis and anaerobic oxidation of reduced metals, gases and organic compounds coupled with denitrification.

There are numerous oligotrophic sub-alpine lakes surrounding Mt St Helens (Fig. 1), which were dramatically altered by the 18 May 1980 eruption. Some lakes and streams were reshaped, new lakes and numerous hydrothermal seeps emerged. Aquatic environments in the blast zone received massive quantities of ash, soil, wood debris and pyrolized soluble organics from the destroyed forest. Previously oligotrophic lakes became ultraeutrophic and anoxic.

The differences in the chemical and biological characteristics of the Mt St Helens lakes in August and September 1980 compared with before the 18 May eruption generally reflected the degree of impact. The lakes can be grouped into three categories based on impact: (1) those receiving only ashfall, such as McBride, June and Merrill; (2) lakes in the blowdown or scorch zones, such as Ryan, Boot, Meta, Panhandle, Venus, Island, Hanaford, Fawn and St Helens; and (3) lakes affected by mud and debris flows, including Spirit, North and South Coldwater, Castle Creek and other new lakes formed by mudflows damming the Toutle River. The heavily impacted lakes near the crater and in the path of mudflows soon became anaerobic due to increased microbial activity fuelled by the high concentrations of dissolved organic carbon (DOC), sulphur compounds and metals entering the lakes, with the result that massive levels of reduced metals, gases and low molecular

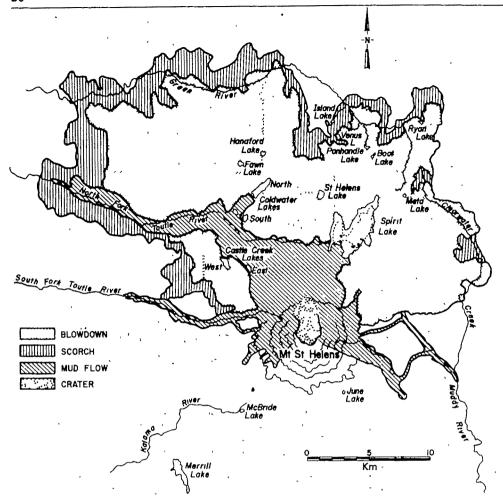

Fig. 1 Map of the lakes in the region surrounding Mt St Helens, showing areas of blowdown, scorch and mudflows. The lakes outside these zones received ashfall but were not in the blast zone.

weight organic compounds were mobilized into the water column. Lakes in the blowdown or scorch zones of the blast area maintained aerobic surface layers over anaerobic hypolimnia. A thermocline was present in lakes in blowdown and scorch zones. Lakes outside the blast zone, which received only ash, have changed the least and remain oxygenated.

All lakes near the volcano have received periodic input of volcanic ash, of dacitic composition, consisting primarily of silica

and aluminium oxides^{1.2}, and mainly of sand size³. Elements of potential biological significance in the ash include Fe (3.7%), P (0.10%), Mn (0.07%) and Mo (1.9 p.p.m.). Leaching experiments using a water/ash ratio of 10:1 in aerobic conditions yielded no decrease in pH and released into solution the following nutrients (in p.p.m.): SO_4^{-2} (57), PO_4^{-3} (3), Mn (0.4), Fe (0.01) and Mo (>0.005)^{1.2}. Most of the constituents of the ash are insoluble in aerobic conditions.

Data are from sampling on 10 August, 19 August, or 11 September 1980. The methods used for chemical measurements are reported in the references given in parentheses: O₂ (16), CO₂ (17); Fe²⁺ (18); Mn (19); PO₄P, NH₄, NO₂, NO₃ and DON (20); total P (21); DOC (22); N₂O (23); and H₂, CO and CH₄ (using a modification of the procedures in ref. 24). ND, no data.

^{*}Surface water temperature at Spirit Lake on 19 May 1980, the day after the major cruption, was 34 °C (T. Casadevall, personal communication). Surface temperature measured on 4 April 1980 was 4 °C (R. C. Wissmar, personal communication). Historical data indicate that typical temperatures for the middle of May would be ~10 °C. The surface concentration of DOC on 4 April 1980 was 0.83 mg Cl⁻¹ in Spirit Lake (R. C. Wissmar, unpublished data) Surface values for DOC on 30 June, 11 August and 19 August 1980 were 39.9, 39.9 and 51.1 mg Cl⁻¹ respectively.

Data are from sampling on 10 August, 19 August, or 11 September 1980. Total bacterial counts were determined using epifluorescent microscopy²⁵. Manganese-and sulphur-oxidizing bacteria were counted using a medium of the following composition (in g): NaCl, 2.6; KCl, 0.88; MgCl₂, 0.56; MgSO₄, 0.76; CaCl₂, 0.1; Na₂HPO₄, 9; KH₂PO₄, 1.5; NaNO₃, 1.0; Na₂S₂O₃, 5; FeSO₄·H₂O, 20×10⁻³; MnSO₄·H₂O, 150×10⁻³; Bacto yeast extract (Difco), 0.01; trace element solution according to ref. 26, distilled water to 11 and adjusted to pH 6.8. Bacto purified agar was dialysed in distilled water to remove soluble organics and 12 g l⁻¹ used. Manganese oxidation was measured using a benzidinium reagent as described in ref. 27. The procedures used for microbiological activity measurement were: N₂ fixation, ref. 28; denitrification, ref. 29; nitrification, ref. 30. The rates of N₂ fixation are only apparent. The acetylene reduction method is an indirect assay for fixation, and the rates have not yet been verified with ¹⁵N₂. Conversion to nanomoles of N₂ fixed was done using an assumed theoretical ratio of 3.0 mol of ethylene produced per mol of N₂ fixed. The theoretical ratio has been reported to vary from 2.0 to 25 (ref. 31). Recently a conversion factor for an anaerobic bacterial population, *Microcoleus chthonoplastes*, in solids was given³² as 5.4. Although the rate of N₂ fixation may be about double the actual rate, it is still much greater than previously reported anaerobic dark fixation rates in a water column. Blue-green algae isolated from lakes in the blast zone included *Pseudanabaena*, *Anabaena* and *Oscillatoria*. Other algae found included *Nitschia*, *Euglena*, *Spirogyra* and an encysting motile, unicellular green alga. ND, no data; NDet, not detected.

In the blast zone, the tremendous heat associated with the eruption (200-350 °C) pyrolized much of the coniferous forest foliage. Throughout the mudflow, blowdown and scorch zones, the concentration of DOC and particulate organic carbon (POC) increased greatly, and the temperature was higher than in nearby lakes outside the blast zone (Table 1). DOC in Spirit Lake increased from $<1.00 \text{ mg C l}^{-1}$ to $>30 \text{ mg C l}^{-1}$, and in North Coldwater and Castle Creek Lakes DOC exceeded 100 and 200 respectively. Heterotrophic microbial activity coupled with the decreased solubility of oxygen at the elevated temperatures quickly consumed the available O_2 , On 30 June 1980, in Spirit Lake, dissolved O_2 was 2.35 mg l^{-1} at 0.25 m (R. C. Wissmar, unpublished data). Throughout August and September no O2 was detected at 0.2 m in Spirit, Castle Creek and North Coldwater Lakes. Lakes outside the path of mudflows but in the blast zone were anaerobic at depth but retained a surface layer with some dissolved O2; those receiving only ashfall were oxygenated throughout.

During the summer and early autumn of 1980, we made four 1-day expeditions to lakes and hydrothermal seeps in the blast zone of Mt St Helens. Ryan, Spirit and North Coldwater Lakes, and the hydrothermal seeps near North Coldwater, were sampled most intensively. The water at all sites was light brown to black in colour due to high levels of sulphides and DOC (Fig. 2). The sediments were actively degassing, giving off methane and other gases, so that in some lakes, such as North Coldwater, the entire surface was continuously bubbling (see Fig. 2). The

bubbles in the lake and at isolated puddles at North Coldwater were collected and analysed and found to consist of $\sim 50\%$ CH₄, 50% CO₂ and trace levels of H₂, CO and N₂O. At the hydrothermal seeps, a black odoriferous liquid with temperatures up to 80° C was emerging and multi-coloured organic films (oil slicks) formed on the surface. The films were periodically broken apart due to violent degassing of, primarily, CH₄, CO₂ and CO (Table 1).

The threefold increase in carbon, phosphorus, sulphur, iron and manganese concentrations, the presence of dissolved gases and the microbial activities in the water suggest that nitrogen cycle processes, including nitrogen fixation, nitrification and denitrification, are important (Tables 1, 2). Dissolved organic nitrogen (DON) concentrations remained low, due to the low C/N ratio of the conifer remains blasted into the lakes and the paucity of nitrogen in volcanic ash4.5, and resulted in low inorganic nitrogen (NH₄, NO₂, NO₃) concentrations, high rates of nitrogen fixation and high DOC/DON ratios. For example, Ryan Lake, which maintained an oxygenated surface layer and algal flora, had a C/N ratio of 52 at the surface but 377 near the bottom. Spirit and North Coldwater Lakes had ratios of 150-250 while that at the hydrothermal seeps exceeded 1,000. The nitrogen concentrations, relative to carbon, phosphorus and sulphur, suggested a nitrogen limitation.

Such a notion was supported by the high rates of phototrophic N_2 fixation and anaerobic dark N_2 fixation (Table 2). Anaerobic dark N_2 fixation was ≤ 230 nM N_2 l⁻¹ h⁻¹ in the surface waters

Fig. 2 Photographs of a, isolated pond near North Coldwater Lake, ~1 week after being filled by rain and showing extensive outgassing and dark black coloration of the water (pond diameter is ~1.5 m) and b, 80 °C hydrothermal seep near North Coldwater creek. Surface of the seep is covered over by a dark, 1-2 cm dark organic sulphide crust which looks like an oil slick.

of North Coldwater Lake. Brezonik and Harper reported a maximum rate of 11 nM l⁻¹ h⁻¹ in one of three lakes with extensive anoxic environments⁶. Such high rates of fixation have not previously been reported in these conditions, and represent a major source of reduced nitrogen to the lakes in the blast zone of Mt St Helens.

The number of bacteria in the lakes and seeps in the blast zone routinely exceeded 10⁸ organisms per ml (Table 2). The manganese/sulphur oxidizing bacteria were repeatedly detected in excess of 106 per ml, a value comparable with the total bacterial counts in eutrophic lakes which generally range from 10⁶ to 10⁷ organisms per ml (ref. 7). Very active methanogenesis occurred in the anaerobic sediments of all lakes and hydrothermal seeps. In addition to ebullition of CH4-rich bubbles at all sites, the dissolved levels ranged from 5 to $>250 \mu M$. High levels of CO, H₂ and N₂O were also detected in all impacted lake waters (Table 1). The exceedingly high concentrations of CO in lake surface waters at ambient temperature and North Coldwater hydrothermal seep waters have not been previously reported. The microbiological processes involved in CO production are not well understood.

Denitrifying bacteria were present in all but the oxygenated surface waters at Ryan Lake, even at 78°C at the North Coldwater seep. The manganese/sulphur oxidizing bacteria were the most abundant denitrifying bacteria, but unlike most stratified and meromictic lakes, where the metal-oxidizing bacteria are detected only at the oxycline, in Mt St Helens lakes the denitrifying metal oxidizers oxidize throughout the anaerobic water column and thus resemble estuarine sediment denitrifiers. Whereas denitrification was occurring in all aquatic environments except the surface waters at Ryan Lake, significant nitrification was limited to the oxygenated zone at Ryan Lake with greatest activity detected in the littoral zone. apparently associated with the nitrogen-fixing cyanobacteria. Significant rates of nitrification were detected in the oxygenated stream that runs into North Coldwater Lake and it is presumed that the stream is the source of nitrate for the lake (Table 2). This interpretation is supported by the reduced rates of denitrification in the isolated pond at North Coldwater.

Overall, the numbers and activities of the bacterial community reflected the widespread anaerobic conditions in the lakes and hydrothermal seeps in the blast zone in August and September 1980. The rates of this microbial biogeochemical cycling in the waters in the blast zone near Mt St Helens rivals those normally found in estuarine muds or the sediments of eutrophic lakes⁸⁻¹⁵. We believe that the rate at which these ecosystems return to the oligotrophism existing before the 18 May eruption will be largely regulated by nitrogen cycle processes associated with bacterial and algal metabolism.

Finally, we believe that many of the heavily impacted lakes and hydrothermal seeps on Mt St Helens represent ideal experimental sites for studying anaerobic microbial processes and chemical transformations which closely resemble those suggested to characterize Archaean reducing aquatic environments.

We thank R. Kepler for graphical and technical assistance, Marie DeAngelis for performing some of the microbiological analyses and L. Gordon for use of laboratory facilities. The US Forest Service provided support and helicopter time.

Speculated cause of interhemispheric oceanic oscillation

J. A. T. Bye & A. H. Gordon

The Flinders Institute for Atmospheric and Marine Sciences, The Flinders University of South Australia, Bedford Park, South Australia 5042, Australia

The study of large-scale correlations of atmospheric and oceanic variables on a supra-annual scale is essential for an understanding of climatic variability. We present here new data on the mean sea-level anomalies in the eastern Indian Ocean which are consistent with supra-annual anomalies in the intensity of the main oceanic gyre, and are negatively correlated with mean sea-level anomalies in the eastern Pacific Ocean. Larger anomalies are induced in the Indian Ocean probably due to its smaller size, and zonal mean stratospheric 50 mbar geopotential heights at 10°N, 20°N and 30°N are better correlated with the Indian Ocean than with the Pacific Ocean mean sea levels. It is speculated that the reported responses are due to a random variation of the monsoonally generated heat transport between the oceans. This variability would give rise to equatorial heat anomalies in each ocean which induce the observed changes in mean sea level, and the coupled changes in the sub-tropical atmospheric circulations.

Figure 1 shows the annual mean sea levels in the Indian Ocean, based on new data for Australian ports¹. A strong coherence clearly exists between the port groups and a lag correlation analysis (J. S. Godfrey, personal communication) indicates that the level changes appear almost simultaneously (within 2 months) throughout. This coherence is similar to that occurring in the eastern Pacific Ocean between San Francisco (38°N, 122°W) and Matarani (17°S, 72°W)2, however, a clear tendency for poleward propagation of the level changes has not been established for the Indian Ocean data. Furthermore on comparing the South Australian port group (for which earlier data are also available) with a group of California ports for the period 1944-75 (Fig. 2), a remarkable negative correlation (correlation coefficient -0.69) between the two records is apparent. Typically each record shows annual mean sea-level variations of ± 5 cm on a period of 3-7 yr. A spectral analysis of each of the records gives multiple peaks of energy in this band.

These data suggest that the mean sea-level variations are due to large-scale phenomena in each ocean, linked by a common mechanism. We propose that the level changes can be interpreted as a strengthening or weakening of the major oceanic sub-tropical anticyclonic gyres, such that for a more intense gyre the anomaly of levels would be positive at the centre, and negative around the coasts, and vice versa. We develop this idea quantitatively using simple models of large-scale ocean circulation^{3,4}. We also speculate on the mechanism that initiates and

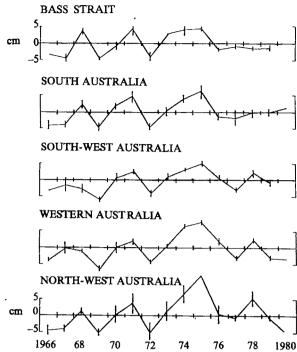

Fig. 1 Deviations in annual mean sea levels in the eastern Indian Ocean for the period 1966–80. Port groups: Bass Strait (Point Lonsdale (38°S, 145°E) and Georgetown (41°S, 147°E)); South Australia (Thevenard (32°S, 136°E), Port Lincoln (35°S, 136°E), Port Macdonnell (38°S, 141°E)); south-west Australia (Albany (35°S, 118°E) and Esperance (34°S, 122°E)); Western Australia (Geraldton (29°S, 115°E), Fremantle (32°S, 116°E) and Bunbury (33°S, 116°E)); north-west Australia (Darwin (12°S, 131°E), Port Hedland (20°S, 119°E) and Carnarvon (25°S, 114°E)). The bars indicate standard deviations between ports; a zero standard deviation is shown when data from only one port are available.

maintains the negatively correlated anomalies in each ocean. We consider first a mechanism for establishing the anomalies.

The Pacific Ocean and the Indian Ocean are connected to the north through the Indonesian archipelago, and to the south by the Southern Ocean. The northern connection lies along the track of the South-East Asian monsoon⁵, which essentially blows towards the north in the northern summer and towards the south in the northern winter, and drives a corresponding circulation in the surface waters of the passages in the archipelago. If there were a random variation in the strength of the monsoon, this would be reflected in a random variation of the heat transport between the two oceans. We suggest that this exchange of heat is the prime cause of the responses shown in Fig. 2, because a positive flux anomaly for one ocean is a negative flux anomaly for the other ocean, and vice versa. Hence the supra-annual anomalies in heat content in each ocean would be negatively correlated, their magnitudes being functions of the monsoonal variability of the previous few seasons. This conclusion is an example of the Slutsky effect⁶ whereby a moving average of a series of random numbers tends to give rise to a series which is quasi-periodic at a period approximately twice that of the length of the moving average.

The differences between the observed records are due to factors in each ocean that effectively give rise to dissimilar moving averages. Notably, the monsoonal heat flux after entering the Indian Ocean is carried westward by the south equatorial current, whereas in the Pacific Ocean its advent is opposed by the north equatorial current with the result that there is a tendency for a ponding of heat anomaly in the western Pacific Ocean. The dispersion of this pond is achieved principally through the equatorial undercurrent, and at times by a sudden discharge which results in an El Nino event⁷⁻⁹. The Indian. Ocean mean sea-level regime indeed extends into the western Pacific Ocean at least as far as Truk (7°N, 151°E)²¹. Note also that although the monsoonal heat exchange for geographical

reasons is primarily an interhemispheric exchange between the southern Indian Ocean and the northern Pacific Ocean, the effect of heat anomalies along the Equator is transmitted to the general circulations of both hemispheres.

In a baroclinic ocean the anomalies in heat content are reflected in surface level changes through the presence of a sub-surface reference level which remains approximately isobaric during the variability. Thus we hypothesize that monsoonally generated changes in ocean heat content in the equatorial regions are the primary mechanism for the induction of the observed anomalies of mean sea level. In particular, in the equatorial regions the depth of the reference level is $\sim 300 \, \mathrm{m}$ (ref. 10), from which it is deduced that temperature anomalies of $\pm 1 \, ^{\circ}\mathrm{C}$ would induce mean sea-level anomalies of $\pm 5 \, \mathrm{cm}$, an increase in level corresponding to an increase in temperature.

Consider next the implications of the persistence of the equatorial anomalies for the general circulations in the ocean and the atmosphere. First, the vorticity balance in the oceanic anticyclonic gyres requires that a cold anomaly (a negative mean sea-level anomaly) must be balanced by an increase in the anticyclonic wind stress curl. In fact, for an ocean gyre in a rectangular basin (latitudinal width L, meridional width M), which is driven by an anomalous zonal wind stress distribution, $\tau = -\tau_0 \cos \pi y/M$, an approximate expression of the anomaly of sea level on the perimeter of the basin, except along its western boundary, (assuming no change in the mass of water in the basin) is

$$\eta \sim -\frac{\tau_0}{\rho g H} \frac{f}{\beta} \frac{L}{M}$$

where ρ is the density of seawater, g is the acceleration due to gravity, $f = 2\Omega \sin \phi$ is the Coriolis parameter in which Ω is angular speed of rotation of the Earth, and ϕ is latitude, $\beta = df/dy$ (0y towards the north), and H is the depth of the reference level. Thus, assuming L = 10,000 km, M = 3,000 km, $\rho = 1,000 \text{ kg m}^{-3}$, $g = 10 \text{ m s}^{-2}$, H = 300 m, $|f| = 0.3 \times 10^{-4} \text{ s}^{-1}$, $\beta = 2 \times 10^{-11} \text{ m}^{-1} \text{ s}^{-1}$, a negative anomaly of mean sea level of 5 cm would induce an increase in the stress contrast between the trade winds and the westerlies $|2\tau_0|$ of 0.05 N m⁻². This value is of the order of 25% of the annual mean contrast of 0.2 N m⁻². It is significant that the only latitudinal variation in the (geostrophic) expression for η lies with f and H, and thus η is predicted to be of similar form at all latitudes in agreement with the data (Fig. 1). The observed similar magnitudes of the anomalies at all latitudes suggest that the reference level $H \propto f$, an inference consistent with oceanic thermocline theory¹². As L is smaller in the Indian Ocean than in the Pacific Ocean, and η is probably larger (Fig. 2), the expression for η indicates that the induced changes in τ would be more significant in the Indian Ocean than in the Pacific Ocean.

In addition to the redistribution of mass within the ocean basins due to the gyral circulation, there is an exchange of mass between the ocean basins brought about through the inverse barometer effect¹³ due to changes in atmospheric pressure. These level changes (ζ) are quite well correlated within the Indian Ocean (Table 1). The ratio of the standard deviations

Table 1 Standard deviations of annual mean sea level and atmospheric pressure in the Indian Ocean for the period 1966-80

Port Group	$(\overline{\eta^2})^{1/2}$ (mm)	Atmospheric pressure station	$(\overline{\zeta^2})^{1/2}$ (mm)	Correlation coefficient between η and ζ
North-west Australia	48	Darwin	6	0.77
Western Australia	38	Perth	8	0.54
South Australia	33	Adelaide	12	0.93

 $\zeta = -P_{\rm a}/\rho g$ is the anomaly of mean sea level arising from the inverse barometer effect, η is the observed anomaly of mean sea level.

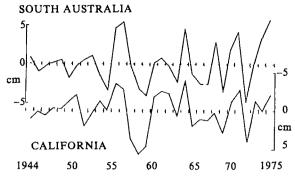

Fig. 2 Deviations in annual mean sea levels on the coasts of South Australia and California for the period 1944-75. Port groups: South Australia (Thevenard, Port Lincoln and Port Macdonnell (1959-75) and Port Adelaide (Outer Harbor 35°S, 138°E, 1944-70); California (San Francisco (35°N, 122°W), Los Angeles (34°N, 118°W), La Jolla (33°N, 117°W) and San Diego (33°N, 117°W)). The records for each California port²¹, and for the South Australian port group^{1,21} were detrended before the calculation of the deviations. Note the scale for the California port group is inverted.

 $(\overline{\zeta^2}/\overline{\eta^2})^{1/2}$ gradually increases from north to south, but even for South Australia, the inverse barometer effect accounts for only a small proportion of the variability in mean sea level.

Assuming that the anomaly of atmospheric pressure has the form, $P_{\bullet} = P_0 \sin \pi y / M$, and applying the geostrophic relation, $\rho_{\mathbf{z}} f u_{\mathbf{z}} = -\partial P_{\mathbf{z}} / \partial y$ in which $\rho_{\mathbf{z}}$ is the surface density of air, and $u_{\mathbf{z}}$ is the anomaly of the surface geostrophic wind, it can be easily shown that the anomalous difference in velocity between the trade winds and the westerlies is $|2\pi P_0/Mf\rho_a|$. Thus, substituting $P_0 = 1$ mbar (Table 1), $\rho_a = 1.2 \text{ kg m}^{-3}$, and $|f| = 10^{-4} \text{ s}^{-1}$, this velocity difference is 2 m s⁻¹, which, assuming a surface drag coefficient of 1.3×10^{-3} (ref. 14) is equivalent to an anomalous stress contrast between the trade winds and the westerlies of 0.06 N m⁻², in excellent agreement with the calculation based on the gyral circulation.

Note that the supra-annual behaviour of the atmospheric general circulation in the Indian Ocean was described in 1925 by Kidson¹⁵ using data for the period 1890-1923. Kidson selected a period of 36 months which he called 'a natural period of action and reaction' as being representative of the major variability. This period is somewhat less than periods (36-60 months) usually adduced from Pacific Ocean data in later studies¹⁶. The two data sets, however, may be reconciled through the discussion of the interaction between the two oceans given here.

We now present new data on tropical stratospheric geopotential heights¹⁷. The zonal annual mean anomalies for 10°N, 20°N and 30°N are all greater in magnitude than the surface pressure anomalies (Table 1), and are well correlated with the mean sea-level data (Table 2). The magnitudes of the correlation coefficients are higher with the South Australian than with the California mean sea-level data, the former being negative and the latter positive. It seems therefore that the zonal mean stratospheric pressure anomalies are in phase with the tropospheric pressure anomalies in the Indian Ocean, rather than linked barotropically with the Pacific Ocean pressure anomalies.

Table 2 Standard deviations of zonal annual mean geopotential heights at 50 mbar, and 10°N, 20°N and 30°N, for the period 1958-75, and the annual mean sea level for California and South Australian ports

		Mean sea	lev e l		
Latitude (°N)	Geopotential height $(p^2)^{1/2}$ (gpm)	California ports $(\eta^2)^{1/2}$ (mm)	South Australian ports $(\eta'^2)^{1/2}$ (mm)	coef	relation ficients tween p and n'
10 · 20 30	18 17 15	24	32	0.33 0.43 0.48	-0 55 -0 58 -0.64

An increase of 1 gpm at the sea surface would lower sea level, by the inverse barometer effect, 1 mm.

This remarkable observation is consistent with an earlier conclusion that the changes in the atmospheric general circulation would be more significant in the Indian Ocean than in the Pacific Ocean. Thus the Indian Ocean climatic signature would be more likely to be impressed on the zonal stratospheric data. Gordon¹⁸ has already reported a highly significant period of about 37 months from a spectral analysis of the monthly anomalies of the stratospheric data, suggestive of Kidson's conclusions for the surface Indian Ocean data. The period possesses greatest power between longitudes 120° and 180°E. Joseph¹⁹ has also found an approximate triennial oscillation in the wind at 100 mbar in the equatorial regions of Asia and Africa. In the peak westerly phase of the oscillation the subtropical westerly wind belt of the Northern Hemisphere penetrated southwards as far as or even beyond the Equator. He found that these incursions appeared to coincide with the failure of the Indian summer monsoon.

We have discussed evidence for a coupled long period interhemispheric oscillation of the ocean and the atmospheric, but the fundamental question is what maintains the oscillation. It may be argued that the ocean is simply responding to the atmospheric southern oscillation which has a similar variability to that deduced from the oceanographic data²⁰. We suggest, however, that the oceanic anomalies are induced by the variability of the monsoonally generated oceanic heat flux, the effect of which is to modulate the vorticity balance of the sub-tropical oceanic gyres. This argument has the important corollary that the subtropical atmospheric circulation must also change sympathetically to support the changes of ocean vorticity.

Thus our proposed mechanism implies that the ocean is the active partner in the supra-annual variability discussed which is characterized in the ocean by an interhemispheric oscillation, and in the atmosphere by the southern oscillation.

We thank Professor G. W. Lennon for use of the Mean Sea Level Data Bank, Dr J. S. Godfrey for early discussions on mean sea levels around Australia, and Dr R. A. D. Byron-Scott for comments. The stratospheric data set was provided by Professor K. Labitzke.

Phanerozoic land-sea and albedo variations as climate controls

Clive F. Burrett

Geology Department, University of Tasmania, Box 252C, Hobart, Australia 7001

It has been suggested 1-8 that variations in the latitudinal distribution of land and sea have been important in controlling climate, especially the initiation of glacial epochs, through geological time. It is thought that surface albedo may be increased and ice caps initiated by the placement of land (and hence snow cover) near the poles^{2,6} or by the placement of land in low latitudes^{4,5,7} or the placement of land with extensive deserts in low latitudes⁸. I document here the relevent Phanerozoic land-sea variations based on recent global palaeogeographical reconstructions⁹, to assess total surface albedo variation and use these data to test the above mentioned hypotheses.

Palaeocontinental reconstructions for the Cambrian to the Triassic (570-200 Myr) have been attempted using all reliable palaeomagnetic data available in May 1981. These maps (Fig. 1) were constructed using the smallest subdivisions of geological time allowed by the data (epochs, early, medial, late Cambrian and so on). As usual with such palaeomagnetically defined reconstructions, longitudinal placement is often uncertain (especially during the early Palaeozoic) whilst latitudinal position is usually constrained to within ±10°, though for several blocks the precision may be much better. Fortunately, palaeoclimatic hypotheses are based almost solely on palaeolatitude. The palaeolatitudinal positions of certain continental blocks (North and South China, South-East Asia, Kolymia¹⁰) are uncertain for much of the Phanerozoic and their positions have been plotted by interpolating between and extrapolating beyond the currently available palaeomagnetic data. The distribution of

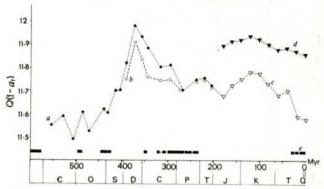

Fig. 2 Variation of $Q(1-a_{\rm T})$ (solar radiation absorption) at Earth's surface through the Phanerozoic. See ref. 8 for details of calculation. a, \blacksquare , $Q(1-a_{\rm T})$ values assuming no deserts or, for Permo-Trias, only those areas known from geological evidence to have been desert from the geological record; b, \bigcirc , values with desert prescribed $10^{\circ}-30^{\circ}$; c, \triangle , post-Triassic trend from ref. 8 assuming no deserts; d, \triangle , post-Triassic trend from Barron et al.8 assuming deserts $10^{\circ}-30^{\circ}$; e, major Phanerozoic ice ages.

Palaeozoic and Triassic epicontinental seas was then plotted using over 3,000 recent references.

The distribution of epicontinental seas is critical in consideration of past albedo as these seas have often almost completely inundated certain large continental blocks and they cannot be ignored as was done by $Cogley^{7.11}$. Palaeogeographical atlases 12,13 based on outmoded data and preconceptions, although still used by some $^{8.14,15}$ have not been used here. A preliminary approximation of major land surface types (deserts, forests and so on) has also been attempted mainly from a synthesis of the sedimentological and palaeobotanical literature. Thus the Cambrian-Triassic surface albedo variations shown in Fig. 2 should be as accurate as is possible from the current literature. To ensure comparability with the work of Barron et al. 8 a plot of $Q(1-a_T)$ is given (Fig. 2) rather than albedo, where Q is the total solar radiation received over the total area of a latitudinal belt and a_T is the surface albedo. Thus $Q(1-a_T)$ is the amount of absorbed radiation at the surface of the Earth.

Values of albedo for various surface types and sea at different latitudes are those given in Barron $et\,al$. Snow is not prescribed as there is little geological evidence for such cover. Prescription of snow cover between 60° and 90° for the early Carboniferous decreases the $Q(1-a_T)$ from 11.883 to 11.771. All land is prescribed a desert albedo before the Devonian. The first land plants are probably late Silurian and although lichens may have covered the early Palaeozoic land surface there is no evidence for this and a desert landscape is considered more probable. The advent of abundant land plants during the Devonian decreased the surface albedo (increased $Q(1-a_T)$) appreciably (Fig. 2).

Thus the early Palaeozoic was a time of high surface albedo with $Q(1-a_{\rm T})$ values similar to or lower than those of today (Fig. 3). However, major early Palaeozoic glacial periods are known only in the late. Ordovician-medial Silurian of Africa and South America. Probable early Ordovician glaciation in Argentina is localized and there are no records of a medial Ordovician glaciation. Geographically restricted ice caps were probably present in South America and, perhaps locally, in Africa 17-19,20. A surprisingly high $Q(1-a_{\rm T})$ value is evident during the Devonian reducing to slightly lower values during the Carboniferous. However there is no obvious correlation between high surface albedo (low $Q(1-a_{\rm T})$) values and the onset of the major glacial periods during the Ordovician, Carboniferous and Tertiary.

If the latitudinal distribution of the land and sea is plotted (Fig. 3) for epochs preceeding ice-age initiation then no obvious correlation is found.

A low latitude terrestrial aggregation occurred in the late Cambrian (Fig. 3c) and certainly reduced $Q(1-a_T)$ (Fig. 2).

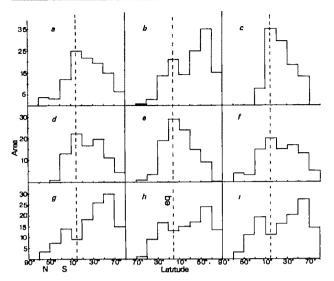

Fig. 3 Histograms of land area with respect to 20° palaeolatitude increments. Area $\times 10^6$ km². eq. Equator; a, early Cambrian; b, medial Cambrian; c, late Cambrian; d, early Ordovician; e, medial Ordovician; f, late Ordovician; g, early Carboniferous; h, medial Carboniferous; i, late Carboniferous.

However, no major ice cap was formed during the late Cambrian or early Ordovician although this may be due to a lack of high latitude land (Fig. 3c,d). Another near-equatorial aggregation of land occurred during the medial Ordovician (Fig. 3c), lowering the $Q(1-a_T)$ value and was succeeded by the major late Ordovician ice age at high latitudes. Thus the Cambro-Ordovician data suggest that ice-cap initiation requires both high albedos, generated by deserts at low latitudes, and sufficient land at high latitudes for ice to accumulate. An increase in absorbed radiation in the mid-Silurian (Fig. 2) may have been sufficient to end the ice-age. Unfortunately, such a scenario cannot be applied to the initiation of the late Carboniferous-Permian glaciation. Low surface albedo values preceded the glacial event during the Devonian and early Carboniferous mainly due to a relative dearth of low latitude land (Fig. 3). Similarly no obviously special configuration of land preceded the initiation of the southern ice-cap during the Oligocene^{8,21}. Thus the data presented in Figs 2-4 show that no obviously simple correlation exists between the latitudinal distribution of land and total surface albedo for epochs immediately preceding the initiation of ice-caps and a more complex explanation involving cloudcover albedo and interactions with other major climate determinations may have to be developed.

I thank C. Eastoe and B. Stait for invaluable help.

Climatic conditions deduced from a 150-kyr oxygen isotope-pollen record from the Arabian Sea

E. Van Campo*, J. C. Duplessy† & M. Rossignol-Strick*

*Laboratoire de Palynologie CNRS, LA 327, Université des Sciences et Techniques du Languedoc, 34060 Montpellier Cedex,

†Centre des Faibles Radioactivités, Laboratoire mixte CNRS-CEA, 91191 Gif-sur-Yvette, France

The correlation reported here of oxygen-18 and pollen records from off-shore marine cores1 enables the history of the nearby continental vegetation, which is controlled by climate, to be examined within the frame of the standard oxygen isotope stratigraphy. Core MD 76 135 from the northern Arabian Sea recovered sediments ranging from oxygen isotope stage 1, Holocene, to stage 6 before 128 kyr BP. Compared with the distribution of modern pollen, low sea-level glacial intervals contain well-preserved pollen which indicate saline littoral, arid and steppe inland conditions. High sea-level interglacial intervals are characterized by savanna-type vegetation. Pollens which are climatically diagnostic and wind-transported indicate distant source areas and reflect the intensification of low-level opposite air flows: the summer south-west monsoonal flow during the last interglacial and the beginning of the present interglacial, and the winter north-east trade winds during the last glacial maximum.

In present climatic conditions, the monsoon system dominates the atmospheric circulation over the Arabian Sea with seasonal low-level wind reversal following the latitudinal migration of the Intertropical Convergence Zone. In winter (October-May), steady but not very strong, dry north-east trade winds blow from Asia (Fig. 1). In summer (May-October), the cool, moist, steady and stronger southwesterlies, which are fed by the Southern Hemisphere winter south-east trade winds^{2,3}, bring heavy monsoonal rainfall to the south and east Asiatic continent

These low-level winds transport pollen from the continents to the ocean where it is eventually deposited in deep-sea sediments. Interpretation of pollen spectra in the Arabian Sea sediments relies on the present-day seasonal distribution of pollen in the air over the Arabian Sea, which identifies both its geographical source area and the wind responsible for its transport. We have studied this present-day distribution by collecting pollen with air filters on board ships travelling along the coasts^{6,7}. The cotton gauze filters are impregnated with silicon oil which collects and retains the mineral particles and pollen grains. They are renewed as often as necessary according to the nearby continental vegetation zones. In Table 1 we summarize data from the coast of Somalia during the summer monsoon and the winter trades. The pollen percentages refer to the total pollen.

Along the coast of Somalia, a 10-day record in July-August shows that the low-level south-west wind carries the highest percentages of Cyperaceae, Euphorbiaceae, Podocarpus and Olea. These taxa are derived from East Africa where the rainfall follows the migration of the Intertropical Convergence Zone of the tropical easterlies, and from the Ethiopian Highlands where rainfall originates in the African monsoon from the Atlantic Ocean⁸. They are well-dispersed East African pollen types^{9,10}.

Along the coast of Arabia, a 7-day record in November yielded mostly Chenopodiaceae and Artemisia pollen grains. The north and north-east low-level air flow suggests an origin in the Arabian desert and the Beluch and Iranian plateaux. The Thar desert does not appear as a source area, as in its southern

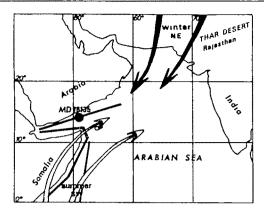

Fig. 1 Location of core MD76135. Arrows indicate low-level seasonal wind flow. Lines indicate ship-routes with pollen collection on air-filters. Solid line: winter air-filters (cruise Orgon IV of R/V Jean Charcot in November 1977, cruise Osiris IV of M/S Marion Dufresne in November 1979). Double lines: summer air-filters (cruise Osiris IV of M/S Marion Dufresne in July-August 1979).

part, the pollen rain does not include large amounts of these taxa¹¹.

As already observed in the Sahara¹², aeolian pollen transport is effective over very long distances, and its influence is dominant in arid zones. There, ground dust and pollen are resuspended in the atmosphere by diurnal thermal turbulence, uplifted to 2,000 m or more, and then transported by strong (but not necessarily prevailing) winds¹³. Over the Atlantic, dust of Sahara desert origin has been estimated¹⁴ at 260×10⁶ tons per year. There is no estimate of the amount of dust from Somali, Arabian and Thar deserts over the Arabian Sea, although the importance of wind in the transport of clay minerals and quartz to the Arabian Sea bottom is recognized¹⁵. The high frequency of haze (solid aerosol) over the north-west Arabian Sea in summer16 indicates mobilization by thermal turbulence, and the low-level steady strong south-west flow¹⁷ suggests a Somali origin. However, occasional north-west storms from Arabia⁴ probably contribute to the haze. In winter, the haze disappears¹⁶. The steady, weak, low-level winds from the north, north-east and north-west would transport quartz dust from the Thar and Arabian deserts into the Arabian Sea18. The low-level air flow probably picks up a great deal of pollen from the littoral zone. Accumulated over several seasons in the inland deserts, dust and pollen would be uplifted to higher altitudes and then, feeding the low-level flow, settle progressively on the sea surface.

This preliminary present-day aeolian pollen survey, which is the means to interpret the climatic variations from the pollen record in Arabian Sea sediments, shows that the two conspicuously opposite climatic and wind-regime patterns are traceable by pollen: pollen collected in summer off Somalia indicates a south-west origin, and in winter off Arabia, a north, north-east and north-west origin.

To document the response of this monsoonal system to the changing boundary conditions during the late Quaternary, we studied core MD76135, collected at 14° 26'6" N, 50° 31'3" E, 1,895 m water depth (Fig. 1). We have measured the 18 O/ 16 O ratio of the planktonic foraminiferal species Globigerinoides ruber and the benthic foraminiferal species Cibicides wuellerstorfi. Analyses were performed using a Micromass 602C mass spectrometer and an experimental procedure described elsewhere 19 . Results are expressed as δ^{18} O defined by the relationship:

$$\delta^{18}O = \left[\frac{(^{18}O/^{16}O) \text{ sample}}{(^{18}O/^{16}O) \text{ PDB})} - 1\right] \times 1,000$$

where PDB is the Chicago PDB-1 standard. No correction has been applied to take account of *Cibicides* departure from isotopic equilibrium²⁰ as this single benthic species has been analysed continuously. Twenty-nine samples were routinely

treated for pollen analysis²¹ and yielded an average of 250 pollens each.

The isotopic records of the planktonic and benthic foraminifera show, as usual, several oscillations. These δ^{18} O variations closely match those of other cores from the Atlantic²², Pacific and Indian Oceans²³, in agreement with the hypothesis that the major signal in these records reflects isotopic changes in the ocean water mass resulting from the waxing and waning of continental ice sheets²⁴.

Following Emiliani²², interglacial stages are identified by odd integers increasing with age and glacial stages are identified by even integers also increasing with age. Isotopic stage 2 corresponds to the last glacial maximum centred about 18 kyr ago, whereas stage 5 represents the last interglacial as observed in equatorial areas²². Stage 5 has been divided into five substages, of which the oldest, 5e, correlates with the Eemian interglacial of north-west Europe²⁵⁻²⁷. Isotopic substage 5e is poorly represented in core MD76135: while glacial isotopic stage 6 is well represented, there is a hiatus corresponding to the transition from stage 6 to interglacial substage 5e, and the lower part of the substage 5e. The upper part of substage 5e is represented by 10 cm of sediment. The sedimentary record is continuous above that level (Fig. 2).

Core MD76135 has provided a well documented pollen diagram. The relative abundance of pollen taxa is shown in Fig. 2. Dominant taxa include Chenopodiaceae which are arid and halophilous and can have a double source area, either inland desert²⁸ or littoral sebkhas²⁹, the dominant source in our marine record. Gramineae and Cyperaceae reflect the environment of the Sudanese savanna. These three dominant taxa originate in the near-shore and inland vegetation. The pollen diagram also contains various less abundant taxa which are presented in Table 2 according to their phyto-geographical source area and their ecology: humid tropical; from open woodland to mangrove, tropical montane (Olea, Podocarpus), from East Africa, Ethiopia and Yemen, Sudano-Sahelian savanna in Somalia, Sahelian near-shore steppe in Arabia and Somalia, Mediterranean subarid steppe (mostly Artemisia) from the Middle East plateaux. All the taxa are still extant in the area.

Figure 2 (right-hand side) shows variations in the pollen groups most diagnostic of climate and wind-regime (Table 2, first five columns): East African total humid tropical taxa carried by south-west winds, dry tropical Sahelian taxa from near-shore steppe, Mediterranean steppe taxa from the north-east. The three dominant taxa of the diagram are excluded (Gramineae, Cyperaceae, Chenopodiaceae). Thus the diagnostic taxa are expressed as percentages of a partial sum which represents only ~20% of the total pollen sum.

The comparison of the pollen and isotopic records of core MD76135 shows that interglacial substage 5e is marked by high relative frequencies of the Sudanese savanna and humid tropical pollen taxa which include the long distance transported tropical African Montane *Podocarpus* and *Olea* signalling a strong south-west monsoonal air flow, while Chenopodiaceae, Sahelian steppe and Mediterranean steppe *Artemisia* pollen decrease. We interpret this period to be both warm and humid. The lowest part of post-glacial isotopic stage 1, early Holocene, around 8 kyr BP at 130 cm core depth, is also characterized by

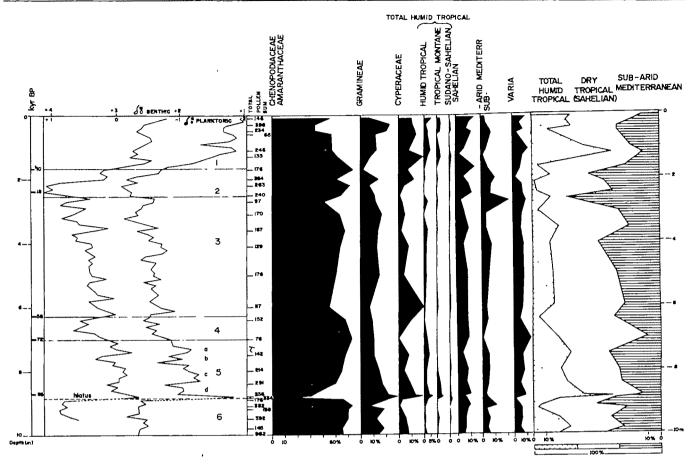

Fig. 2 Oxygen isotope and pollen record of core MD76135. Ages are estimated from refs 24, 41, 46. On the right column, total humid tropical taxa include humid tropical, tropical montane and Sudano-Sahelian taxa of the main diagram. All pollen relative frequencies are calculated on the total pollen sum.

highly increased amounts of humid tropical and Sudano-Sahelian savanna taxa, indicating a stronger south-west monsoonal flow, an increased Indian monsoon, and more moisture in Somalia. The late glacial-early Holocene (Bølling-Alleröd to Boreal) was the most humid period since the last glacial maximum in all the equatorial latitudes of the planet³⁰, a response to the insolation peak in summer centred at 11 kyr BP, controlled by the variations of the Earth's orbital parameters³¹. In East Africa, this humid phase, clearly displayed by high lake levels and pollen records^{30,32-40}, begins at 12.5 kyr BP, and its peak is reached from 10 to 8 kyr BP. In our record, around 12.5 kyr BP, at 200 cm core depth immediately after the most arid last glacial

maximum at 220 cm core depth, there is a sign of locally increased moisture fostering the Somalia savanna, and of intensified long distance transport of humid tropical pollen. The same level of moisture and wind intensity is found during isotopic stage 3, while during isotopic stage 5, it is always significantly higher. Between the incipient humidification (around 12.5 kyr BP) and the Holocene main humid peak, the cold/dry Younger Dryas (11–10 kyr BP), clearly marked in Fig. 2 by the step of the isotopic curve at the transition of stages 2 to 1 (ref. 41), at 165-m core depth, correlates with local desiccation (decline of Gramineae-Cyperaceae, rise of Chenopodiaceae and Sahelian), and weakening of the monsoonal wind (decline of

Ephedra Erodium Ombelliferae Plantago	Anacardiaceae Betula Caryophyllaceae Cleome Convolvulus Cordia Corylus Euphorbia Fagonia Fagus Labiateae Myrica Nitraria Papilionaceae Plumbaginaceae Pinus Rhus

humid tropical). This is also widely displayed in Africa³⁰. In the western Arabian Sea, early Holocene faunal planktonic assemblages point to lower sea-surface temperatures and stronger south-west monsoon air flow⁴². Today, the summer south-west air flow induces strong upwelling along the Somalia and Arabia coasts, which is responsible for the extensive seasonal cooling of the Arabian Sea⁴³. In Rajasthan, north-west India, lake levels and pollen records point to the most humid monsoonal period between 10.3 and 9.5 kyr BP (ref. 44) still as humid but with more winter rain of Mediterranean origin from 9.5 kyr BP, until 5.0 kyr BP (refs 44, 45).

Glacial isotopic stages 6, 4, end of 3 and most clearly stage 2, the last glacial maximum are marked by low relative frequencies of humid tropical taxa and high relative frequencies of taxa from the Mediterranean steppe. These latter taxa originate from the north and north-east, indicating stronger north-east trade winds and increased aridity. High sea-surface temperatures estimated from faunal analysis in the western Arabian Sea during the last glacial maximum reflect reduced oceanic upwelling, as the south-west air flow was weaker42

The arid halophilous Chenopodiaceae are abundant throughout the core and reflect mostly littoral vegetation²⁹. They decrease during interglacial isotopic substage 5e (together with the Sahelian steppe) and the upper part of stage 1 (late Holocene), when the sea level was high. However, in the Holocene, the most humid period as indicated by the highest relative frequency of savanna and humid tropical taxa, occurred at 130 cm core depth, before the Chenopodiaceae minimum at 50 cm core depth. During substages 5e to 5a. Chenopodiaceae increase while humid tropical taxa decrease. Glacial stages 6, 4 and 2, and also the transition from stage 2 to 1, Younger Dryas⁴¹, are characterized by high Chenopodiaceae and Sahelian steppe and low humid tropical taxa values, pointing to conditions drier than those of today. It is suggested that Chenopodiaceae reflect the salinity increase of the littoral water-table during glacial periods²⁹. Aridity lowers the freshwater table level in the newly uncovered, lower, regressive littoral strip. The seawater, which is then more saline, impinges for hydrostatic readjustment. Extensive littoral sebkhas vegetated by Chenopodiaceae result. This accounts for the very good positive correlation of Chenopodiaceae with the δ^{18} O enrichment and explains why the Chenopodiaceae Holocene minimum (maximum transgression) occurs significantly later than the Holocene most humid period.

We thus conclude that this marine pollen diagram from the arid tropical zone depicts the fluctuations of the intensity of the seasonally reversing low latitude wind systems, and of the local moisture, and correlates littoral aridity with sea-level variations. These fluctuations correlate with the global climate changes as indicated by isotopic stratigraphy. The intensity of the monsoonal winds seems to respond mainly to the variations of the insolation, controlled by the Earth orbital parameters, being maximum when the insolation is strongest⁴⁶. Glacial periods were arid in southwestern Asia and at low latitudes, and the north-east trade winds were intensified against a decreased monsoonal flow. In the tropics, as evidenced by the most detailed Holocene record, incipient interglacial stages were the most humid periods: the south-west monsoonal flow was intensified, over the Atlantic and Africa, and over the Arabian Sea and India. The insolation peak developed low pressures over the tropical continents and heavy rains resulted. Meanwhile, the middle and high latitudes, more influenced by the northern ice-sheets, also had warm summers⁴⁷ although dry, and reached their humidity peak later.

We thank J. Antignac and B. Le Coat for help in the isotopic analyses, D. Duzer for technical assistance in the air-filters pollen analyses, W. Prell for a careful review and useful comments. Cruises Osiris II and Osiris IV of the M/S Marion-Dufresne have been supported by TAAF. Cruise Orgon of the R/V Jean Charcot has been supported by CNEXO. Support for laboratory studies was provided by CNRS, DGRST and CEA. (All of us are supported by CNRS.)

A-nor-steranes, a novel class of sedimentary hydrocarbons

Ger van Graas, F. de Lange, J. W. de Leeuw & P. A. Schenck

Delft University of Technology, Department of Chemistry and Chemical Engineering, Organic Geochemistry Unit, De Vries van Heystplantsoen 2, 2628 RZ Delft, The Netherlands

As part of our investigations of Cretaceous black shales¹ we have analysed samples from a location near Aqualagna in the north central Apennines, Italy (43°39' N, 12°43' E). The saturated hydrocarbon fraction of one sample, a dark-grey shale of Upper Barremian age (115 Myr BP), contains novel series of steranes, which have been identified as C_{26} – C_{28} 5β (H)- and $5\alpha(H)$ -A-nor-steranes. Because these compounds are structurally related to 3β -hydroxymethyl-A-nor-steranes which have been found in some sponges, we suggest here that these steranes might be biological markers for certain types of sponges.

The Upper Barremian sample has an organic carbon content of 9% and was Soxhlet extracted with toluene/methanol (1/3,

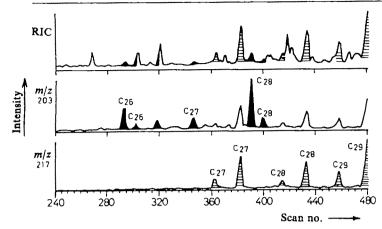

Fig. 1 Part of the reconstructed ion chromatogram (RIC) and of mass fragmentograms of m/z 203 (indicative of A-nor-steranes) and m/z 217 (indicative of steranes). Temperature programme: $150-280 \,^{\circ}\text{C}(4 \,^{\circ}\text{C min}^{-1})$.

v/v; 20 h). The hexane-soluble part of the extract was separated by column chromatography over silica/alumina using hexane, toluene and toluene/methanol (1/1, v/v). The saturated hydrocarbons were isolated from the hexane fraction by Ag⁺-TLC (Merck silicagel impregnated with a 3% solution of silver nitrate in water/methanol) using pentane as a developer. Gas chromatography-mass spectrometry was performed on a Varian 3700 gas chromatograph equipped with a 25-m glass capillary column (i.d. 0.25 mm) coated with CP-sil-5 coupled to a MAT 44 quadrupole-mass spectrometer operating at 70 eV (mass range: m/z 50-500; cycle time, 2 s).

The saturated hydrocarbon fraction of the shale sample contains series of n- and isoprenoid alkanes, steranes, 4-methylsteranes and hopanes. Also present are a series of compounds with mass spectra that show a main fragment ion at m/z 203 (Fig. 1) and molecular ions at m/z 358 (Fig. 2a), 372 and 386. These mass spectra are similar to those of steranes with m/z 217, 218 shifted to m/z 203, 204 respectively and m/z 149 shifted to m/z 135.

Based on the mass spectra we assumed the unknown compounds to be a series of modified C_{26} , C_{27} and C_{28} steranes with 14 mass units missing from the nucleus and with side chains comparable to the common C_{27} , C_{28} and C_{29} steranes. From the shift of the fragment ion m/z 217—in steranes representing the ABC-ring part of the molecule²—to m/z 203 and the shift of the fragment ion m/z 149—in steranes ascribed to an AB-ring fragment³—to m/z 135 it can be deduced that a methylene group from ring A or B or the C_{19} methyl group is not present in these compounds. The presence of a characteristic peak at m/z 262 in the spectrum of the C_{26} unknown compound suggests that the missing carbon atom is the 19-methyl group or a methylene group of ring A. Ion m/z 262 in the spectrum of cholestane results from B-ring cleavage⁴ and therefore a substantial change

in the intensity of m/z 262 should be expected in the case of a B-nor-sterane.

To test our hypothesis the following compounds were synthesized⁵⁻⁹ (conversion of 19-hydroxycholest-4-en-3-one into 19-nor-cholesterol was achieved according to a reaction scheme obtained from Organon) (Fig. 3): 19-nor-cholestane (the synthesis yielded three compounds with identical mass spectra, probably A-B ring junction isomers), $5\alpha(H)$ -A-nor-cholestane and $5\beta(H)$ -A-nor-cholestane. The mass spectra of the 19-nor-cholestanes differed from those of the A-nor-cholestanes in the presence of a prominent peak at m/z 148 (Fig. 2d). The mass spectra of the $5\alpha(H)$ - and $5\beta(H)$ -isomers of A-nor-cholestane are different with regard to the ratios of M⁺ and M⁺-15 (Fig. 2b, c).

Mass spectrometry (Fig. 2) and coinjection on a capillary column coated with SE-52 showed that the first eluting C_{26} -unknown compound (Fig. 1) is identical to 5β (H)-A-nor-cholestane. The second unknown C_{26} -compound coeluted with 5α (H)-A-nor-cholestane but the mass spectrum of this less abundant unknown was not intense enough to compare it in detail with the spectrum of the synthetic compound. Therefore the second eluting C_{26} -compound is tentatively identified as 5α (H)-A-nor-cholestane. From these results it seems likely that the hydrocarbon fraction of the shale sample under investigation contains series of C_{26} , C_{27} and C_{28} , 5α (H)- and 5β (H)-A-nor-steranes.

In addition to these $5\alpha(H)$ - and $5\beta(H)$ -A-nor-steranes there is one other relatively intense peak in the fragmentogram of m/z 203 (Fig. 1, scan 318). The mass spectrum of this compound does indeed show an intense peak at m/z 203 but its identity is unknown at present. An assignment of this compound to a C_{20} -epimer of an A-nor-sterane seems very unlikely as the regular steranes in this sample are exclusively present in the natural 20R configuration.

It is now clear that the nor-steranes in DSDP sediments previously assigned tentatively as 19-nor-components¹⁰ are in fact A-nor-steranes (J. McEvoy, personal communication).

The unsaturated hydrocarbon fraction of the sample contains diasterenes, hopenes and in addition a series of compounds with mass spectra similar to those of diasterenes but with a base peak at m/z 243 instead of m/z 257 (ref. 11). Considering the presence of A-nor-steranes in the saturated hydrocarbon fraction we suggest that this series of unsaturated compounds is a series of A-nor-diasterenes. However, this suggestion has to be confirmed through the synthesis of the proper compounds.

As abiotic ring contraction of six-membered rings has not been reported in sediments, the presence of A-nor-steranes in the sample under investigation is thought to be the result of the input of related compounds showing this skeleton.

Sterols with a $5\alpha(H)$ -A-nor-nucleus and a 3β -hydroxymethyl group have been found as major sterols in several sponges $^{12-14}$. With one exception these sponges all belong to the family Axinellidae 14 . It is not known, however, whether these sponges already existed during the Cretaceous. The A-nor-sterols are

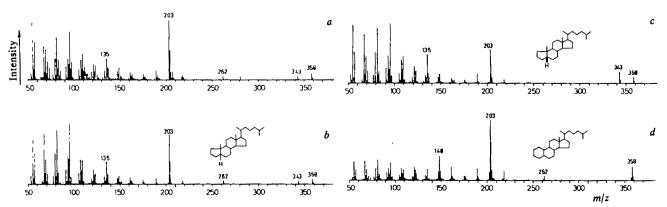

Fig. 2 Mass spectra of a, the first eluting unknown C₂₆-compound (scan 293, Fig. 1); b, synthetic 5β (H)-A-nor-cholestane; c, synthetic 5α (H)-A-nor-cholestane; d, synthetic 19-nor-cholestane.

Synthetic pathways for: a, 19-nor-cholestane from 19-hydroxy-cholest-4-en-3-one (refs 6-8); b, A-nor-cholestane ($5\alpha(H)$ and $5\beta(H)$) from cholestanone $(5\alpha(H))$ and $5\beta(H)$ (refs 6-9).

formed by the sponges through ring contraction of the dietary sterols¹⁵. It seems possible that the A-nor-steranes present in this Cretaceous sample are the ultimate diagenetic products of 3β -hydroxymethyl-A-nor-steranes, assuming that the 3β hydroxymethyl group is removed (through microbial action?) and that isomerization at C5 occurs at some stage of diagenesis resulting preferentially in the more stable $5\beta(H)$ -isomer.

Molecular mechanics calculations using the EAS force field¹⁶ by J. M. A. Baas (Delft University of Technology) showed that model compound I (A-B cis) is thermodynamically more stable than model compound II (A-B trans) by 1.9 kcal mol⁻¹ (Fig. 4). See also calculations on the 8-methyl-hydrindanes in ref. 17. The presence of sponges seems to contradict the supposedly anoxic environment of sedimentation of black shales. However, some sponges are tolerant of very low levels of oxygen¹ Moreover, black shale formation does not necessarily imply the existence of a thick anoxic water layer but can also occur when anoxic conditions are restricted to the sediment itself or to a thin (few millimetres) water layer at the bottom. We therefore suggest that these novel series of sedimentary hydrocarbons might be useful markers for certain types of sponges.

We thank P. L. de Boer for the sample and Dr F. J. Zeelen (Organon, Oss) for 19-hydroxycholestenone. This research is supported by the Netherlands Foundation for Earth Science Research (AWON) with financial aid from the Netherlands Organisation for the Advancement of Pure Research (ZWO).

Chemi-ionization in oxyacetylene flames

A. N. Hayhurst & H. R. N. Jones

Department of Chemical Engineering, Cambridge University, Pembroke Street, Cambridge CB2 3RA, UK

The identity of the first ion formed in hydrocarbon flames has created much discussion. Two species have been favoured 1-7, produced in the chemi-ionization processes:

$$CH + O \rightarrow CHO^{+} + e^{-} \tag{1}$$

$$CH^{+} + C_{2}H_{2} \rightarrow C_{3}H_{3}^{+} + e^{-}$$
 (2)

Reaction (2) is usually taken to involve electronically excited CH, in which case reaction (2), like reaction (1) with ground state CH, is close to thermoneutral. Experimental evidence has been claimed for both. For example, Peeters et al.3 prefer reaction (1), while Calcote et al.4 have suggested that reaction (2) is necessary to explain the abundance of ions in fuel-rich flames. Interestingly, evidence for CHO+ has been obtained1.3.5 from either non-acetylene flames or those with low C/O ratios, while evidence for $C_3H_3^+$ appears 2,4,6,7 in fuel-rich acetylene flames, where [C₂H₂] is high and [O] is low. We describe here a mass spectrometric study of fuel-rich acetylene flames, and attempt to clarify the picture. Evidence is presented which suggests that both reactions operate simultaneously in oxyacetylene flames.

Experimental details have been given elsewhere⁸. Briefly, pre-mixed laminar fuel-rich acetylene/oxygen/argon flames were burnt at atmospheric pressure on a single quartz tube. We are concerned here with three such flames, all having similar velocities and temperatures (~2,300 K), but with C/O ratios of 0.80, 1.02 and 1.09. With C/O = 1.02 and 1.09 a 'feather', that is, an extended luminous mantle, is visible downstream of the main reaction zone. Soot is only produced in the flame with C/O=1.09. Ion concentrations were measured along each flame axis using a quadrupole mass spectrometer. Such concentration profiles could be obtained for single ions, or, by removing the d.c. component of the rod voltage, of the total ion current.

Various classes of positive ion emerge in this study. All hydrocarbon ions $C_x H_y^+$ reach peak concentration in the reaction zone or just downstream of it. In fact, they are of two types: aromatic ions, which decay extremely rapidly in the feather, and polyacetylene ions, which persist as far as the feather does and then decay quickly in the burnt gases.

However, major oxygen-containing ions, including H₃O⁺, CHO⁺ and C₂H₅OH₂⁺, have concentrations which peak in the burnt gases and then persist for several millimetres downstream. This is typified by the profiles for C₃H₃⁺ and CHO⁺ shown in Fig. 1. Figure 1a is for C/O = 0.80, where no feather is present. $C_3H_3^+$, which is the most abundant of the $C_xH_y^+$ species, reaches peak concentration in the reaction zone and disappears very rapidly in the burnt gases, while CHO+ peaks some 3 mm downstream of the reaction zone. As the fuel-oxygen mixture is enriched, the feather appears for C/O > 0.9; with C/O = 1.02(Fig. 1b) the feather is ~5 mm long. C₃H₃⁺ still peaks in the reaction zone (RZ) and is present throughout the feather, peaking again before decaying at the feather tip. However, CHO+ reaches maximum concentration downstream of the feather tip, and is not detected at all in the reaction zone. Soot is actually seen in the richest flame studied here (C/O = 1.09,Fig. 1c), which makes the length of the feather difficult to estimate. However, CHO+ peaks some 10 mm downstream of the reaction zone. Thus can an ion which is in such low concentrations and only seen in detectable quantities so far downstream, really be the only primary chemi-ion?

Figure 2, a plot of total positive ion current against distance, provides more information. All profiles are undoubtedly double-peaked, noticeable more as a shoulder for C/O = 0.8. The first peak is in the reaction zone, while the second appears just downstream of the feather tip. In fact, these two peaks correspond spatially to maxima for the ions $C_3H_3^+$ and CHO^+ .

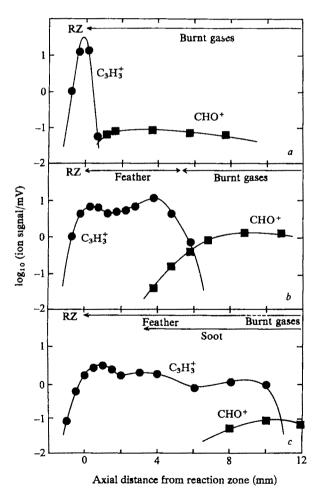

Fig. 1 Concentration profiles of $C_3H_3^+$ (\blacksquare) and CHO⁺ (\blacksquare) in acetylene/oxygen/argon flames plotted as \log_{10} (ion signal) against distance along flame axis. Zero distance corresponds to the primary reaction zone (RZ), as denoted by the emission of C_2 . Flames are: a, unburnt gas composition (by volume): $[C_2H_2]/[O_2]/[Ar] = 0.80/1.0/6.4$, so that C/O = 0.80; b, $[C_2H_2]/[O_2]/[Ar] = 1.02/1.0/5.3$, C/O = 1.02; c, $[C_2H_2]/[O_2]/[Ar] = 1.09/1.0/5.8$, C/O = 1.09.

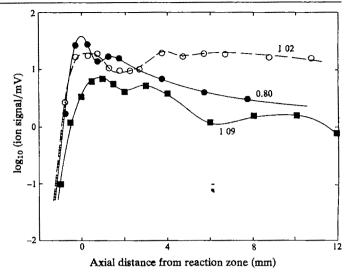

Fig. 2 Total positive ion intensity profiles in acetylene/oxygen/argon flames, with C/O ratios as shown, plotted as log₁₀ (ion signal) against axial distance.

The second increase in total ion current indicates a fresh production of ions by a different mechanism, rather than chemical production from existing hydrocarbon ions. The profile plotted in Fig. 2 for the sooting flame (C/O=1.09) is actually the sum of masses 0-170 AMU, rather than the total abundance of all positive ions. There is a distinction between these two quantities in this flame, which arises from the presence (but in sooty flames only) of positive ions having masses beyond the range of this instrument. The form of Fig. 2 avoids any complications from these heavy ions.

The two maxima in Fig. 2 and their relationship with the profiles of $C_3H_3^+$ and CHO^+ in Fig. 1 lead us to propose that two primary ionization mechanisms operate in fuel-rich acetylene flames, namely reactions (1) and (2). As the C/O ratio is increased, it is expected that the concentration of acetylene will grow, while oxygen atoms will decrease. Consequently, the rate of reaction (1) (C[CH][O]) will decrease, while that of reaction (2) ($C[CH^*][C_2H_2]$) will increase. The evidence above suggests that reaction (2) can become faster than reaction (1), although both are operating. The result is two separated zones of ion production. In lean acetylene flames and systems using other fuels, $[C_2H_2]$ will probably be low enough for reaction (1) to dominate. In fact, in very lean acetylene flames (CO = 0.06), very little $C_3H_3^+$ is observed at all⁹. With CHO⁺ as primary ion, hydrocarbon ions may be produced by processes such as:

$$CHO^{+} + CH_{2}O \rightarrow CH_{2}OH^{+} + CO$$

 $CH_{2}OH^{+} + C_{2}H_{2} \rightarrow C_{3}H_{3}^{+} + H_{2}O$

This may explain the second (more downstream) peak in the profile of the hydrocarbon ions.

These results confirm and expand the work of Tse et al.⁶, who reported that (1) CHO⁺ and H₃O⁺ peak concentrations were a long way downstream of C₃H₃⁺, and (2) hydrocarbon ions were pyrolytic in origin and preceded true oxidation. The chemistry of neutral radicals in the feather seems to have received little attention in the past, although much is known of stable products ^{10,11}. Ogden has made emission spectroscopic measurements directly on CH* and indirectly on H, OH and O; they indicate that [CH*] has a double-peaked profile which maximizes in the reaction zone and again early in the feather, while H, OH and O maximize in concentration just once, further downstream in the feather. However, as excitation of CH is chemical rather than thermal, no inferences should be made concerning ground state CH, which participates in reaction (1). Some quantitative data on this species would be useful in testing the viability of two chemi-ionization processes operating simultaneously. Even so, our conclusion that there

are two chemi-ionization processes agrees with what is known about the concentration profiles of the relevant neutral species. We thank the British Gas Corporation for financial assistance.

Preservation of unsaturated fatty acids in Palaeogene angiosperm fruits and seeds

Karl J. Niklas*, Bruce H. Tiffney† & A. Carl Leopold‡

Despite the rapidity with which unsaturated fatty acids (UFAs) undergo autoxidation by atmospheric oxygen. Priestlev et al. have reported that oleic and linoleic acids persist in Zea mays seeds >1,500 yr old. They suggest, on the basis of analyses of progressively older seed samples (78-1,700 yr old), that a small proportion of UFAs may persist in seed tissues over extended periods of time. Here we report chemical analyses of Eocene and Oligocene angiosperm fruits and seeds (30-50 × Myr) which indicate the preservation of significant amounts of unsaturated fatty acids (9.6-17.8% of the total lipid content) in these ancient organic remains. The fossils contain larger proportions of polar unsaturated fatty acids, derived primarily from membranes, than those derived from storage lipids, suggesting a preferential oxidation of unsaturated fatty acid constituents of the membranes. We suggest that morphological characters, such as thin seed coats and the accessibility of the inner seed structure to the environment, may influence the extent of unsaturated fatty acid preservation.

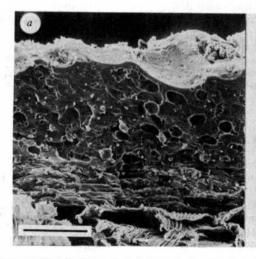

Fossil material was collected from two localities of different age (Table 1). Seeds of Zanthoxylum ornatum were obtained

from the Middle Eocene (~45 Myr old) Geiselthal Flora of East Germany2. Other fossils were collected from the Brandon Lignite of West-Central Vermont, the flora of which is now being investigated3,4. The age of the Brandon flora is uncertain, but is presently inferred to be Middle to Late Oligocene (30 Myr old). In both cases the fossils were found as compactions (threedimensional structures composed of original organic material) preserved in brown coal. These coals are the result of the compression of peat deposits in the swampy environments in or around which the parent plants grew. The fossils most probably were preserved in a waterlogged, anaerobic environment since the time of their deposition. The preservation is excellent in all cases, for example, seeds of Zanthoxylum rhabdospermum and Euodia costata retain the non-lignified secondary thickenings of the inner wall of the inner integument5. Four of the five fossils examined are seeds. Of these, Z. ornatum2, Z. rhabdospermum and Euodia lignita 5 possess sclerotic, semi-vitreous seed coats of 8-30 cell layers, 150-700 µm thick (Fig. 1a). In contrast, the seed coat of Vitis macrochalaza4 is thinner (1-2 cell layers, 60-225 µm thick), and is more leathery than vitreous^{6,7} Symplocos sp., in contrast to the other fossils examined, is a trilocular endocarp bearing remnants of thin-walled seeds. Each locule opens to the exterior through a large pore, exposing the inner as well as the outer face of the fossil to ground water.

Representative fossils were collected from moist lignite, stored in glass vials, and subsequently crushed to a fine powder; to prevent oxidation of potentially preserved UFAs, we added an antioxidant (2,6-di-tert-butyl-p-cresol; 50 µg ml-1). Extraction of fatty acids and hydrocarbons used the saponification procedure of Farrington and Quin8. Samples of the fossil material were refluxed (1 h) with 0.5 M KOH in 95% methanol/benzene (1:1 v/v). Non-saponifiable lipids were separated from saponifiable compounds by adding water to the saponification solvent mixture and extracting with petroleum ether. The aqueous phase of this separation was acidified and saponified lipids were extracted with petroleum ether. Fatty acids were isolated by methylating the dried residue of the saponifiable lipid extract using the BF3-MeOH procedure of Metcalfe et al.9. Polar lipids (phoso- and glycolipids) were separated from storage lipids using the analytical technique of Priestley et al.10 and Dittmer and Willis11. Fatty acid methyl esters were extracted with petroleum ether and purified by TLC on silica gel G plates. Identification of UFAs used combined gas and mass spectroscopy.

Microbial activity in the fossil specimens examined was evidenced by the detection of trace amounts of isomeric cisvaccenic acid (18: 1w7), which is an abundant bacterial constituent12. Mass spectroscopy, however, revealed that the most prevalent 18:2 acid in our samples was 18:1w9 oleic acid. From comparisons of microbially decomposed seed tissues of some of the fossil taxa found as fossils, and the geolipids isolated

Fig. 1 a, Scanning electron micrograph of the seed wall of a broken Z. rhabdospermum seed (Brandon, Vermont). The spirally-thickened cells of the inner integument (at bottom) are succeeded by those of the bilayered outer integument, the inner portion of which consists of approximately five levels of bricklike cells and the outer of four to five levels of isodiametric sclereids. Scale bar, 50 µm. b, Scanning electron micrograph of the base of a trilocular endocarp of Symplocos sp. (Brandon, Vermont). Note the three pores, each of which leads to a locule carrying the remains of a thin-walled seed. Scale bar, 1 µm.

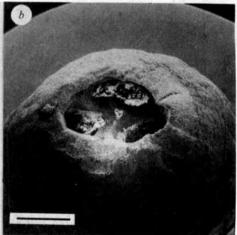

Table 1 Palaeobotanical data for fossil specimens examined

Specimen	Family	Locality	Age	Average wall thickness (μm)	No. of cell layers
Zanthoxylum ornatum Chandler	Rutaceae	Geiselthal, East Germany	Middle Eocene	300700	20-30+
Zanthoxylum rhabdospermum Tiffney	Rutaceae	Brandon Lignite, Vermont	Middle Oligocene?	200-400	8-20
Euodia costata Tiffney	Rutaceae	Brandon Lignite, Vermont	Middle Oligocene?	150-250	815
Symplocos sp	Symplocaceae	Brandon Lignite, Vermont	Middle Oligocene?	650-1,000	14-20
Vitis macrochalaza Tiffney	Vitaceae	Brandon Lignite, Vermont	Middle Oligocene?	60-225	1-2

Table 2 Representative UFA content of fruits/seeds of the Brandon Lignite

THE RESERVE THE PROPERTY OF TH							rated fatty acids†
				atty acids		Polar	Storage
Specimen	(mg per g seed)	16 0	18.0	18.1	18 · 2	subfraction	subfraction
Zanthoxylum ornatum	7 4* (0.5)	36 0* (0.1)	47.9 (0.1)	10.3 (0.2)	3.7 (0.5)	6.3	7.7

Euodia costata	109 (0.9)	35.2 (0)	43 2 (0)	9.6 (0)	4.8 (0)	5.5	8.9
Symplocos sp	5 6 (0 7)	39 7 (0)	49.7 (0)	9.6 (0)	_	1.3	8.3
Vltis macrochalaza	77 (05)	40 3 (0)	44 8 (0)	8.4 (0)	4.0 (0)	5.6	6.8

Fatty acid methyl esters were identified on (1) a 2 m × 1.5 mm glass column packed with 20% FFAP on 70-80 mesh crom W-AW-DMCS operated isothermally at 190 °C. and (2) a 2 m×1.5 mm glass column packed with 15% diethylene glycol succinate on Anakrom ABS 110/120 mesh, operated isothermally at 145 °C.

from the fossil specimens examined here and from their associated inorganic strata, we conclude that biotic contamination of our specimens was minimal. The geolipid (UFA) profiles presented are interpreted, therefore, as being representative of the endogenous biochemical profiles of the fossil taxa.

With the exception of Symplocos, the fossils contain significant percentages of linoleic (C_{18 2}) and oleic (C_{18 1}) acids (Table 2), indicating that complete oxidation of the UFA fraction has not occurred despite the age of the specimens. The lack of C_{18 2} in the endocarp of Symplocos may be ascribed to the thin-walled nature of the seeds and their continuity with the external environment through the locular pores (Fig. 1b). While the relative proportion of palmitic acid (C_{16 0}) is greater than that of C_{18 0} in Zanthoxylum seeds, the remaining specimens show a repeated pattern in the relative abundance of the four major acids detected $(C_{180} > C_{160} > C_{181} > C_{182})$. This differs from the relative proportion of these acids found in modern counterparts $(C_{182} > C_{18.1} > C_{180} > C_{160})$, and is interpreted as evidence for the enrichment of the C₁₈₀ acid component by the oxidation of C_{18 2} and C_{18 1} constituents. Consistent with this notion is the observation that Symplocos endocarps lack detectable C_{18 2} and yield the highest percentage of C_{18 0} (Table 2). A comparison of the proportion of fatty acids isolated from the polar lipids (predominantly of membrane origin in modern seeds) and from storage lipid subfractions (Table 2) provides evidence for the preferential degradation of membrane

Our study of the UFA content of these fossils indicates that a degradation of the membrane UFA subfraction parallels the absence of preserved membrane structure. Transmission electron microscopy of fossil specimens from the Brandon Lignite revealed little or no demonstrable protoplasmic details. The deterioration of membranes may well have resulted from lipid peroxidation and the consequent perturbation of the characteristic biomolecular (lipid-protein) membrane infrastructure. Electron microscopy has demonstrated that some membrane structure survives in ancient seeds and leaf tissues, indicating that sufficient membrane lipids may persist to maintain the bilayer configuration 13,14. Priestley et al. reported that the UFAs of the storage lipid and membrane lipid subfractions of maize seeds 1,700 yr old were equally susceptible to oxidation. The apparent preferential preservation of storage lipid UFAs in the fossil material examined here could reflect some differential distribution of naturally occurring antioxidants in the tissues. The ability of tocopherols, in low concentrations, to prevent lipid peroxidation is well documented15. Gaillard16 has reviewed

the roles of antioxidants in lipid metabolism. Note that tocopherols accumulate in plastids and that their synthesis and that of storage lipids in seeds may be separate, independent processes. It is noteworthy that plastids appear to be the most persistent organelles in fossil leaf tissues^{13,14}.

The preservation of such labile components in fossil reproductive structures >50 Myr old, confirms the previous speculation1 that a residual, long-lasting UFA component will survive in old seed tissues. It is also possible that other labile constituents of chemotaxonomic significance may be preserved in reproductive organs such as seeds and fruits from the localities examined. Geochemical analyses of other fossil specimens have revealed a vast array of biochemical constituents commonly thought to be too labile to survive over extended geological time¹⁷. The data presented here can be placed in the context of reports documenting the preservation of flavonoids18, chlorophyll derivatives¹⁹ and various phenolics²⁰ in comparably old fossils and fossil strata. Further chemical and ultrastructural analyses of Brandon Lignite fossils and specimens from other localities may elucidate the biochemical processes involved in fossilization as well as provide information relevant to the taxonomy of problematical angiosperm genera.

We thank Drs D. H. Mai and H.-J. Gregor for providing specimens of fossil Zanthoxylum. This research was supported by a NSF grant to J.N.

Vision has a role in *Limulus* mating behaviour

R. B. Barlow Jr, L. C. Ireland & L. Kass*

Marine Biological Laboratory, Woods Hole, Massachusetts 02543, USA

In 1928 Hartline noted that the lateral eye of the horseshoe crab, Limulus polyphemus, was an admirable preparation for research in visual physiology. Since that time, extensive studies of Limulus have yielded fundamental understandings of visual processes and of sensory processes in general1.2. However, except for demonstrations of primitive phototaxis3-5, studies have not yet revealed a possible role of vision in the animal's behaviour. We have further investigated the problem by studying mating behaviour, the only known behaviour exhibited by Limulus in its natural habitat. We report here that horseshoe crabs discriminate form and contrast during mating: males are attracted to painted cement castings of the female carapace and other forms, the degree of attraction depending on the form and contrast of the castings, and on the time of day. The discrimination of form may result from information transmitted by several sensory systems but the discrimination of contrast requires vision.

Along the eastern coast of North America, *Limuli* move in from deep water in the spring and build nests on protected beaches near the water's edge at high tide⁶. Numerous femalemale pairs arrive, together with an excess of males. We observed the activity of males in the vicinity of cement castings placed in the water at a nesting beach.

The cement castings were made from an adult female carapace (27 cm wide), a hemisphere (29.5 cm diameter) and a cube (1.640 cm²). The exposed surface areas of the hemisphere and cube were each equivalent to that of the female carapace (1,365 cm²). Each casting was painted black, grey or white, yielding relative contrasts against sand underwater of -0.70, +0.1 and +0.75, respectively. The average relative contrast of the Limulus carapace against sand was -0.33 ± 0.03 (n = 12). All contrast values were determined by reflection densitometry, using a reflection density guide (Kodak 146 5947) and panchromatic black and white film (Kodak Plus-X). The three different castings, together with three shades of paint, yielded nine experimental objects. Two of each object, giving a total of 18 castings, were placed in random order in a row 4 m below the high-water line on the south side of Mashnee Dike, Cape Cod. Massachusetts. We observed the behaviour of males in the vicinity of each casting during eight high tides, four at night and four during the day.

Figure 1a shows a male Limulus mounted on a black cement casting of the female carapace. The male has mounted the dorsal part of the casting in the usual position for egg fertilization. Some males maintained this position for several hours. Figure 1b shows a single male soon after it approached and made contact with the prosomal region of a grey casting. Figure 1c shows a male mounted on a white casting; four other males hover nearby, apparently searching for an opportunity to mount. The behaviour in Fig. 1 is indistinguishable from that of normal mating. Similar behaviour was observed in the vicinity of every cement casting, but the number of males around a specific casting depended on its form and contrast.

Figure 2a shows that the number of males was greatest around the female models and lowest around the cubes. In each of eight observation periods, males selected female models in preference to hemispheres and hemispheres in preference to cubes. The probability of these results occurring by chance is 3^{-8} ; p < 0.001. The degree of selection was not significantly influenced by time of day. We conclude that male Limuli can

Fig. 1 Male horseshoe crabs in the vicinity of submerged, painted castings of the female carapace. a, A male Limulus mounted on the posterior portion of a black casting in the normal position for egg fertilization. b, A male in contact with a grey casting soon after approaching the model. c, One male mounted on a white casting with four others hovering nearby apparently searching for the appropriate mating position. All photographs were taken during the same night-time observation period with Kodak Plus-X film and flash. The animals and models are under water in each photograph. Note in b the ripples generated on the water surface by the male. The overall length of the black casting in a is 55 cm.

discriminate form. Discrimination of form may be based on tactile or visual inputs, or both.

Figure 2b shows that the contrast of a casting also influences male mating behaviour. The data on male contacts with castings were pooled according to the shade of paint used (black, grey or white). Black castings yielded the highest percentage (40%) of male contacts, regardless of time of day. The attraction of males to the grey castings was also high and almost equal to that of black castings during the day but not at night. Black and grey castings may have attracted most males during the day because they are similar in shade to the female carapace and are clearly visible. Note that the relative contrast of the female carapace against sand is -0.33, which falls within the contrast values of the black and grey castings (-0.7 and +0.1). At night, the low relative contrast of the grey castings against sand may have made them less visible. Indeed, the grey Limulus casting in Fig. 1c is difficult to distinguish from its underwater background. We could not see the grey castings at night but had no difficulty in detecting the white and black castings by illumination from either a new or full moon. The results in Fig. 2b suggest that, when visibility is not a limiting factor, male Limuli are attracted to objects that appear similar in shade to the female carapace.

Taken together, the data in Fig. 2a and b show that males were attracted most to the black Limulus casting and least to the white cube: in each of the eight observation periods, black Limulus castings yielded the highest number of male contacts and white cubes the lowest number.

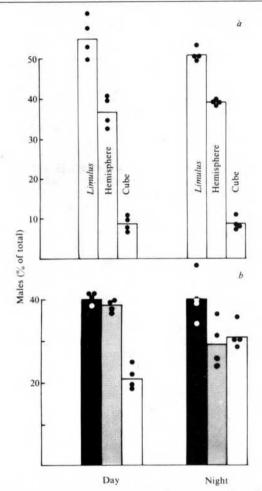

Fig. 2 Percentage of males observed at the cement castings during the day and at night. a. Filled circles indicate the percentage of males observed at each cement form during four daytime and four night-time observation periods. The daytime percentages did not differ significantly from the night-time values. Columns represent the average values. b, Filled and unfilled circles indicate the percentage of males in contact with the black (solid columns), grey (stippled columns) and white (open columns) castings during the same eight observation periods as in a. Columns represent the average values. The black castings attracted the greatest percentage of male Limuli regardless of time of day. The attraction of the grey castings was greater during the day, that of the white castings lower. Results are based on a total count of 6,988 males in contact with the set of 18 castings described in the text. The data were collected during eight high tides as males, in their search for females along the water's edge, approached and explored the submerged castings. Two observers separately surveyed the castings every 5 min during the 3-hr period that the tide covered the set of castings. The day- and night-time data were then summed and normalized.

Blinded animals were not attracted to the cement castings. In one night-time experiment we covered the median and lateral eyes of 75 male Limuli with black acrylic paint. The density of males around the castings fell by a factor of 8, and the distribution of the few animals found near the castings did not match that shown in Fig. 2. This result cannot be considered conclusive because some of the blinded animals buried themselves in the sand after being released at the water's edge. Nevertheless, the results are consistent with the notion that vision has a role in mating behaviour.

Visually guided behaviour is also evident from films taken during the day, which show that male Limuli passing within 2 m of a casting of a female carapace often change orientation and travel directly towards the casting, then explore and attempt to

Vision thus appears to play a part in Limulus mating behaviour, but other sense modalities may also be involved. Our

observations suggest that male animals are attracted to objects by form and contrast. Maintained contact with objects may be based on tactile cues transmitted by a well developed mechanoreceptor system7,8. Chemical cues may also be involved9, but as yet no information on chemical attractants is available.

Circadian rhythms in the Limulus visual system10 may be an integral part of the mechanisms underlying the behaviour reported here. At night a circadian clock in the Limulus brain transmits efferent neural activity to the lateral eyes, increasing the response and decreasing the noise of single photoreceptor cells11. Circadian changes in retinal physiology and anatomy increase the sensitivity of a dark-adapted lateral eye by as much as 30-100 times at night12. High visual sensitivity may adapt the animal for specific nocturnal behaviour such as mating.

Serotonin-activated adenylate cyclase during early development of Schistosoma mansoni

Margaret R. Kasschau* & Tag E. Mansour†

Department of Pharmacology, Stanford University School of Medicine, Stanford, California 94305, USA

Schistosoma mansoni infection is a major parasitic disease which afflicts 200 million people, mostly in developing countries. The parasite has a complex life cycle during which it is parasitic on a snail at the larval stage and on a mammalian host as an adult. In addition, there are two free-swimming stages: miracidia, which must penetrate the snail host, and cercariae, which leave the snail to find the correct mammalian host. On penetration into the mammalian host, the cercaria loses its tail and is referred to as a schistosomule. Adult stages of Fasciola hepatica (liver fluke)1,2 and S. mansoni3 have probably the highest adenylate cyclase activity reported, and in both parasites the enzyme can be activated by serotonin. Studies on Fasciola' have shown that GTP is necessary for serotonin activation. One possible main function of high adenylate cyclase activity is the regulation by cyclic AMP of anaerobic glycolysis, which is the main source of energy in the adult stage of these parasites5 We have compared the activities of adenylate cyclase in different developmental stages of Schistosoma. We report here that the cercariae have low adenylate cyclase activity which responds only poorly to activation by serotonin and GTP. However, in schistosomules cultures in vitro7, we found that within the first 4 days the cyclase system changed from one showing low serotonin activation, similar to that of cercariae, to one of high activity similar to that found in the adults.

Adenylate cyclase activity in adults was compared with that in cercariae. Particle preparations isolated at 2,000g contained

Present address: School of Sciences and Technologies, University of Houston at Clear Lake City, Houston, Texas 77058, USA † To whom correspondence should be addressed.

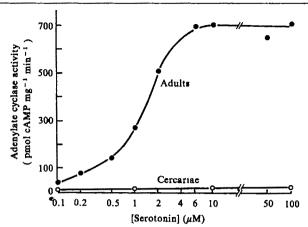

Fig. 1 Serotonin activation of adenylate cyclase from adult and cercaria particles. Representative experiment on adult (●) and cercaria particles (○) in which serotonin was added at the indicated concentrations to adenylate cyclase reaction mixture containing 0.1 mM ATP and 1×10⁻⁵ M GTP. Adenylate cyclase activity was determined as described in Table 1. Basal activity (without activators) for adults was 8 pmol cyclic AMP (cAMP) mg⁻¹ min⁻¹ and <3 pmol cyclic AMP mg⁻¹ min⁻¹ for cercariae.

almost all the cyclase activity. Representative experiments summarized in Table 1 show that when the enzyme was maximally activated with NaF, the specific activity of the cercarial enzyme was $\sim 20\%$ of that of the adult. Serotonin plus GTP caused almost no activation of the cercarial enzyme, whereas it markedly stimulated adult adenylate cyclase. Figure 1 shows the effect of various concentrations of serotonin plus GTP on the enzyme from cercariae and adults. The specific activity of the two enzymes is markedly different even at concentrations as low as $1-10~\mu\mathrm{M}$ of serotonin. The results in Table 1 also show that the poorly hydrolysed GTP analogue, Gpp(NH)p (guanylyl imidophosphate), by itself stimulated the enzyme from both sources, whereas the natural nucleotide GTP had no stimulatory effect. Note that serotonin in the presence of Gpp(NH)p caused significant stimulation of enzyme activity

Adult worms, obtained from hamsters by perfusion 16, were homogenized using a glass homogenizer in 0.25 M sucrose, 5 mM dithiothreitol (DTT) and 1 mM EDTA. Snalls were placed under light to induce shedding of cercariae. Cercariae were concentrated by cooling until swimming stopped, and then centrifuged. The pellet was homogenized in a glass homogenizer with a motorized glass-Teflon pestle in the same buffer as the adults. Both homogenates were spun twice at 2,000g for 15 min each. The final resuspended particles were used as the enzyme source. We determined adenylate cyclase activity using the method of Salomon *et al.*¹⁷, which measures the production of radio-actively labelled cyclic AMP from $\left[\alpha^{-32}P\right]ATP$. ³H-labelled cyclic AMP was added to the mixture after the reaction was stopped to monitor cyclic AMP recovery as described by Salomon et al. 17 under 'method . Assays contained 0.1 M sucrose, 50 mM glycylglycine (pH 7.5), 0.5 mM isobutyl methylxanthine, 5 mH phosphocreatine, 2 mM MgCl₂, 5 mM DTT, 0.02 mM EDTA, 0.1 mM Na₂ATP, 5 U creatinephosphokinase, and \sim 1 μ Ci [α -³²P]ATP. Reactions were initiated with 0.05 ml of particles and the final volume of the reaction mixture, with or without specific activators, was 0.25 ml. All samples were incubated for 10 min at 30 °C. Protein was determined by the method of Bradford 18. from the cercariae, though not as high as that of the adult. In these conditions of enzyme activation, the specific activity of the cercarial enzyme never exceeded 15% of that of the adult.

As there was such an obvious difference in total adenylate cyclase activity (with NaF) and serotonin-stimulated activity between adults and cercariae, the question arose of how rapidly the enzyme develops from low to high responsiveness to serotonin. We therefore studied the enzyme activity in the early intermediate stages of development from cercariae to adults. Schistosomules were prepared and cultured at 36 °C in a 5% CO₂ atmosphere for 10 days according to the procedure of Basch⁷, in medium containing 10% serum and 1 µM serotonin. Representative results for cyclase activity at different stages of development of the schistosomules are shown in Fig. 2. NaF-stimulated adenylate cyclase activity increased after preparation of the schistosomules from the cercariae; such an increase does not appear to be due to the experimental procedure used as preparation of the schistosomules by mechanical means⁸ without exposure to tissue culture media gave the same increase in fluoride-activated enzyme. The most significant change in the adenylate cyclase activity during schistosomule development was the marked increase in serotoninactivated enzyme on the second and fourth days (Fig. 2). While serotonin-activated adenylate cyclase in the cercariae was only 0.8% of NaF-stimulated activity, by the fourth day the adenylate cyclase in the schistosomules could be activated by serotonin to 6% of NaF-stimulated activity. Adenylate cyclase activity of schistosomules that were maintained in culture for up to 10 days showed no further increase in sensitivity to serotonin activation. Enzyme from adult worms grown in vitro also showed activation by serotonin to 6% of total activity (NaF-stimulated), although total activity doubled (Fig. 2). Serotonin-activated cyclase activity was higher in the parasites grown and collected from the hamster host than in schistosomules or in adults grown entirely in vitro (Fig. 2).

We then tested the effect of serotonin activation in the presence of Gpp(NH)p. Figure 3 shows that serotonin in the presence of Gpp(NH)p caused significant activation of cyclase in cercariae and schistosomules, an effect not shared by the natural nucleotide, GTP. Further activation by serotonin had doubled by the second day of schistosomule culture, when it reached a plateau. Note that much of the serotonin activity in

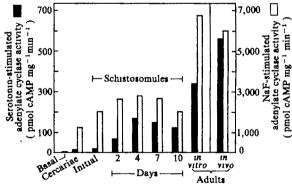

Fig. 2 Activation of adenylate cyclase by serotonin and GTP (left ordinate) and by NaF (right ordinate) at different stages of development. Cercariae from infected snails and adults from hamsters were collected as described in Table 1. Early schistosomules (initial) were isolated from cercariae and cultured according to the procedure of Basch⁷. Adults were prepared in vitro after culturing the schistosomules for 3 months, according to the Basch procedure. Preparation of particles as well as assay of adenylate cyclase were as described in Table 1 legend. Adenylate cyclase activity was measured in a reaction mixture containing 0.1 mM ATP and either 10 mM NaF or 100 µM serotonin with 10⁻⁵ GTP. Adenylate cyclase activity in particles from schistosomules immediately after preparation from the cercariae is indicated by 'initial'. Basal activity for adults was <8 pmol cyclic AMP mg and for cercariae and schistosomules <3 pmol cyclic AMP $mg^{-1} min^{-1}$.

the presence of Gpp(NH)p in these stages of early development is due to the effect of the nucleotide itself. The adenylate cyclase activity of the adult worm (grown either in vitro or in vivo) was still higher than that in the early stages of development, indicating further increase in enzyme activity during development of the parasite to maturity. Serotonin has been reported to stimulate the motility of several trematodes including schistosomes (for review see ref. 9). In the present experiments we observed that cercariae, immediately after shedding their tails, did not respond to the stimulatory action of serotonin. However, after only 2 h in tissue culture medium, schistosomules responded fully to the stimulatory action of the indolamine on motility.

The cercariae of this trematode are short-lived free-living larvae whose main function is to find a suitable warm-blooded host. The results reported here clearly show that at this stage adenylate cyclase activity and its responsiveness to serotonin are extremely low. While the cercaria is a free-living organism in water, it develops to a schistosomule in the host, where it encounters serotonin. We have shown that early in schistosomule development, adenylate cyclase activity becomes higher and its responsiveness to serotonin markedly increases. The adult parasite showed an even greater increase in both total- and serotonin-stimulated adenylate cyclase activity. Thus as the parasite develops to maturity, it gains more adenylate cyclase that is sensitive to serotonin activation. Because of the marked difference between fully serotonin-activated cyclase activity and the maximum capability of the enzyme system in both schistosomules and adults, it is possible that other naturally occurring factors besides serotonin control cyclase activity during development of the parasite. The results suggest that adenylate cyclase is necessary to supply cyclic AMP early in development so as to achieve full parasite maturation. Cyclic AMP has been reported to be important for the development of trypanosomes10 and malarial parasites11, as well as for cell differentiation¹² and proliferation¹³.

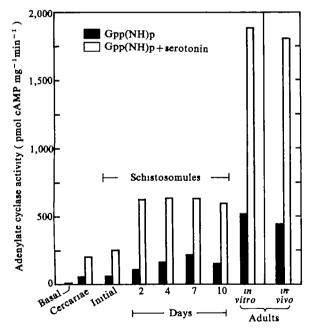

Fig. 3 Activation of adenylate cyclase from schistosomules by Gpp(NH)p with and without serotonin. Representative experiment on cercariae, schistosomules and in vitro and in vivo adults. Schistosomules and adult worms (in vitro) were obtained from cultures, cercariae were obtained from infected snails as described in Table 1, and adults (in vivo) were dissected from infected hamsters. Particles were prepared and analysed as described in Table 1 legend. All adenylate cyclase reaction mixtures contained 0.1 mM ATP and 2×10^{-5} M Gpp(NH)p with or without 100 μ M serotonin, as indicated in Table 1. Basal activity for adults was <8 pmol cyclic AMP mg⁻¹ min⁻¹ and for cercariae and schistosomules <3 pmol cyclic AMP mg⁻¹ min⁻¹.

We reported previously that serotonin activates three key enzymes in the regulation of metabolism in a closely related parasite, F. hepatica: glycogen phosphorylase¹, phosphofructokinase⁶ and cyclic AMP-dependent protein kinase¹ all these enzyme systems, cyclic AMP appears to be involved in enzyme activation and therefore may be crucial for normal development of the parasite in the host. Apparently, the schistosomule synthesizes an adenylate cyclase that is more responsive to serotonin than the enzyme in cercariae. This developmental stage occurs in the first 48-96 h of the schistosomule life cycle, which corresponds closely to the time of complete skin penetration¹⁵ and arrival in the vascular system where serotonin is present. Serotonin-activated adenylate cyclase in the early stages of schistosome development offers sites which are amenable to pharmacological manipulation and which could be used for the selection of more effective antischistosomal agents.

This work was supported by USPHS research grants MH 23464 and AI 16501. We thank Dr Paul Basch and Mrs Natalicia Basch for providing us with infected snails, infected hamsters and schistosomules.

Expression in E. coli of Chlamydia trachomatis antigen recognized during human infection

Wanda M. Wenman & Michael A. Lovett

Molecular Biology Institute, University of California, Los Angeles, Los Angeles, California 90024, USA

Chlamydia trachomatis, a prokaryotic obligate intracellular parasite of eukaryotic cells, has long been recognized as the agent of trachoma, the major infectious cause of human blindness1. In the past decade, clinical investigations have shown that the frequency and severity of chlamydial genital infection parallels that of gonorrhoea, and that C. trachomatis is a major cause of non-gonococcal urethritis, epidymitis, proctitis, cervicitis and salpingitis, as well as conjunctivitis and pneumonia in neonates². Despite the new awareness of its role in human disease, there is a need for improved methods of identification and control of C. trachomatis infections. Progress in these areas awaits a more detailed understanding of the pathogenesis of chlamydial infection, including definition of key antigenic structures recognized in human disease. We have studied the immune response to chlamydial polypeptides during human infection and have found that most infected patients have antibody to polypeptides of molecular weight (M_r) 67,000 (67K), 60K, 40K, 19K and 16K, regardless of infecting immunotype3. We report here the cloning and expression in Escherichia coli of the 19K C. trachomatis polypeptide, an immunogen in human chlamydial infection.

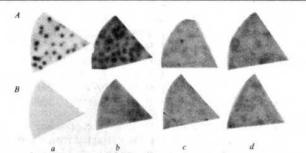

Fig. 1 Clone A4 plaques react specifically with serum from humans having chlamydial infection. Plates containing 100–150 clone A4 plaques were overlaid with nitrocellulose disks for 10–20 min. The disks were cut into quadrants then soaked in 5% OA–TSA (5% ovalbumin in 50 mM Tris-HCl pH 7.5, 150 mM NaCl, 0.15% sodium azide) to saturate unused protein binding sites, and incubated overnight with individual sera diluted 1:250 in 1% OA–TSA. After washing, the disks were reacted with ¹²⁵I-protein A, washed, dried and exposed to Kodak X-Omat AR film between intensifying screens. A, reaction of A4 plaques with sera from infected (a, b) and uninfected individuals (c, d). B, reaction of A1059 plaques with the same four sera.

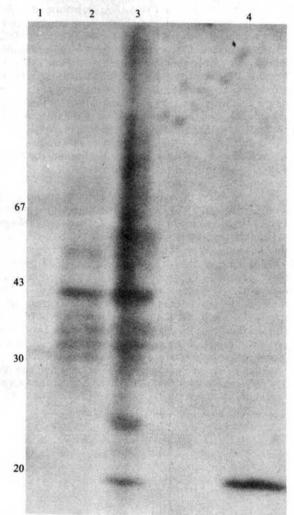

Fig. 2 Autoradiogram of clone A4 'Western' blot. Lysate samples were boiled in 0.0625 M Tris, 2% SDS, 10% glycerol, 0.001% bromophenol blue, 5% β-mercaptoethanol before loading on to 8-20% gradient polyacrylamide SDS gels. After electrophoresis and transfer to nitrocellulose, the blot was probed with the human chlamydial serum used in earlier screening (see Fig. 1a). Radioiodinated molecular weight standards (Pharmacia) are marked on the left ($×10^3$). Samples shown are host $E.\ coli\ Q359$ (lane 1), chlamydial L_1 elementary bodies (lanes 2, 3), and clone A4 grown in broth cultures of Q359 (lane 4). Except for lane 2, which was an older, partially degraded sample, approximately equal amounts of protein were applied to each lane.

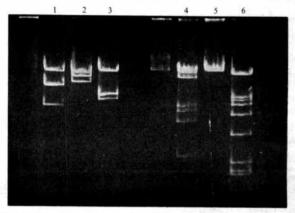

Fig. 3 Restriction endonuclease digests of vector and clone A4 DNA. DNA extracted from purified vector or recombinant phage was digested with various restriction endonucleases in recommended buffers (New England Biolabs). Cleaved DNA samples were then analysed on a 0.6% agarose gel and stained with ethidium bromide. Shown here are λ1059 digested with EcoRI (lane 1), BamHI-digested λ1059 (lane 2), λ1059/HindIII (lane 3), A4/EcoRI (lane 4), A4/BamHI (lane 5), A4/HindIII (lane 6). Fragments were sized using λ/HindIII markers (BRL; data not shown). Unlabelled lanes contain nonreactive clone plaques.

Elementary bodies (EB) of *C. trachomatis* type L₁, grown in HeLa cells, were purified through Renografin (Squibb) to yield EB free from host cell contamination⁴. Chlamydial DNA was extracted from EB in 20% sucrose containing 50 mM Tris pH 7.5, 20 mM Na₂EDTA, 200 μ g ml⁻¹ proteinase K, and 0.7% Sarkosyl at 55 °C for 15 min, followed by further incubation at 37 °C for 45 min. After phenol extraction and equilibrium centrifugation in neutral CsCl, the chlamydial DNA was dialysed against 10 mM Tris pH 7.5, 0.1 mM Na₂EDTA. It was then partially digested with Sau3A I and ligated to BamHI-cleaved vector phage λ 1059 (ref. 5). The ligated DNA was then packaged in vitro⁶ and used to transfect E. coli Q359 which is permissive only for recombinant plaques. Plaques were screened for expression of chlamydial antigens by an in situ radioimmunoassay.

Nitrocellulose disks were placed over the recombinant bacteriophage plaques to absorb plaque-derived protein. The disks were then exposed to serum from a human with chlamydial infection, followed by reaction with ¹²⁵I-labelled protein A of Staphylococcus aureus (Pharmacia) and autoradiography. One plaque which gave a particularly strong signal, designated A4, was chosen for further study (Fig. 1). Plaques of clone A4 reacted specifically with sera from patients having chlamydial infection but showed no reaction with sera from uninfected humans in conditions where plaques of vector λ 1059 (without a chlamydial DNA insert) did not react with sera from patients with chlamydial infection or from control patients.

The nature of the chlamydial antigen encoded by clone A4 was elucidated by 'Western blotting' of total protein from an A4 lysate (Fig. 2). A4 specifies a polypeptide antigen of M_r 19K (Fig. 2, lane 4), identical in size to that of an antigen of C. trachomatis elementary bodies.

DNA from clone A4 was partially characterized by restriction endonuclease cleavage (Fig. 3). As expected, clone A4 has a cleavage pattern which differs from that of the original vector $\lambda 1059$, consistent with an insert size of 15 kilobase (kb).

We have described here the expression in E. coli of a M_r 19 K antigen of C. trachomatis; we have shown previously³ that an antigen of this molecular weight is a consistent immunogen in human chlamydial infection. Antibody to this polypeptide is therefore indicative of chlamydial infection regardless of immunotype, and this could possibly become the basis of simple serotests for chlamydial infection. We believe that cloning the genes for major chlamydial immunogens in human infection provides a powerful tool for studying the immunobiology of this organism. It should be possible, using recombinant sources of

chlamydial antigens, to reproduce by experimental vaccination the pattern of antibody to chlamydial polypeptides found in various chlamydial diseases, and then determine whether this modifies experimental chlamydial disease.

Transformation of the green alga Chlamydomonas reinhardii with yeast DNA

J.-D. Rochaix & J. van Dillewijn

Département de Biologie Moléculaire, Université de Genève, CH-1211 Geneva 4, Switzerland

The development of a transformation system in the green unicellular alga Chlamydomonas reinhardii is important for two reasons. First, a large number of nuclear mutants of this organism have been characterized, including auxotrophs, cytoplasmic and chloroplast ribosome mutants, photosynthetic and flagellar mutants^{1,2}. The isolation of wild-type genes from C. reinhardii and from other plants may be possible by complementation with an efficient transformation system. Second. modification and reinsertion of these genes and their regulatory elements into C. reinhardii cells is likely to provide important insights into their function and regulation. Here, we describe the first successful nuclear transformation of C. reinhardii. A plasmid carrying the yeast arg4 locus and a yeast replication origin^{3,4} has been used to transform a C. reinhardii cell walldeficient, arginine-requiring mutant. In several transformants the yeast gene appears to have integrated stably into the nuclear

The arg7 locus of C. reinhardii was used for selection. It codes for argininosuccinate lyase (ASL), the last enzyme of the arginine biosynthetic pathway, which converts argininosuccinate into arginine and fumarate⁵. In C. reinhardii the enzyme consists of five (±1) identical subunits of molecular weight ~39,000 (ref. 6). The first arg7 mutant of C. reinhardii was isolated by Gillham⁷; several other mutants of this type have since been obtained and characterized8.9. The DNA used for transformation was the plasmid pYearg4 containing a yeast replication origin and the yeast arg4 locus^{3,4}, which is analogous to the C. reinhardii arg7 locus. The 18 kilobase (kb) pYearg4 plasmid contains a single EcoRI site and eight HindIII sites and the arg4 gene is located on the second largest (2.7 kb) HindIII fragment³ (fragment B in Fig. 2h). One important advantage of using this plasmid is that it cross-hybridizes only weakly with nuclear DNA of C. reinhardii, thereby allowing an easy distinction between true transformants and revertants (see below). To avoid using cell wall-degrading enzymes to obtain protoplasts, the cell wall-deficient strain cw15 (ref. 10) was chosen. The double mutant cw15 arg7 was constructed by Dr P. Bennoun.

Cells of cw15 arg7 were treated with poly-L-ornithine¹¹ or polyethylene glycol (PEG), mixed with yeast plasmid and plated on plates containing acetate as sole carbon source¹² (see Fig. 1 legend for experimental details). After 2 weeks small green colonies appeared at a frequency of $\sim 10^{-6}$. Table 1 shows that the poly-L-ornithine method is more reproducible than the PEG method.

As the reversion frequency of arg7 is $\sim 10^{-7}$ (ref. 9), the putative transformants were tested for the presence of yeast plasmid sequences. Total DNA was extracted from these cells and digested with restriction endonucleases. The DNA fragments were electrophoresed on agarose gels (Fig. 1), transferred to nitrocellulose filters according to Southern¹³ and hybridized with radioactively labelled pYearg4 plasmid DNA. Figure 1b shows that a 13.1 kb EcoRI fragment hybridizes with the probe in transformant T2-5. Hybridization of the same probe with undigested DNA produces a smear (Fig. 1d), indicating that the plasmid DNA is integrated in the nuclear DNA of this transformant. The possibility that the plasmid is not integrated but present as a high molecular weight concatemer can be excluded because pYearg4 hybridizes to a nuclear HindIII fragment that is larger than the largest HindIII fragment of pYears4 (Fig. 2) lanes f, h). When total DNA from non-transformed cells is hybridized with the same probe, only one faint band, of lower molecular weight, is apparent (Fig. 1f). When nuclear DNA from non-transformed cells was mixed with one copy equivalent of pYearg4 plasmid per genome, cleaved with EcoRI (Fig. 1g) and hybridized to the probe (Fig. 1h) in order to estimate the copy number of integrated sequences, the intensity of the signal was comparable with that of Fig. 1b. Comparison of the sizes of pYearg4 (Fig. 1h) and the EcoRI fragment of the transformant, which hybridizes to the probe (Fig. 1b), reveals that at least 5 kb of the plasmid DNA have been deleted in the transformant. Similar hybridization patterns are obtained when the ColE1 vector alone or the purified HindIII fragment B of pYearg4 are used as probes (data not shown).

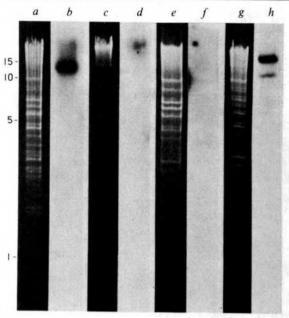

Figure 2a-c displays the hybridization patterns obtained with another transformant, T8-3. Whereas one major signal is visible with EcoRI-(Fig. 2a) or HindIII- (Fig. 2c) digested DNA, no strong band is detectable with undigested DNA (Fig. 2b), probably because of the poor transfer of larger fragments of DNA. As in the previous case it can be concluded from these data that a portion of the yeast plasmid has inserted itself into the nuclear DNA. Note that the EcoRI fragment of T8-3 hybridizing to the probe differs in size from the corresponding fragment of T2-5 and that the hybridization patterns obtained with HindIII digests of the DNAs of the two transformants are different (Fig. 2c, e, g). It appears therefore that the integration of pYearg4 in the two transformants has either taken place at different sites in the nuclear genome or at the same site with different deletions and/or that rearrangements of the plasmid sequences have occurred.

Table 1 Summary of transformation experiments

Expt	DNA used for transformation (5 µg)	No of a Method I	arg ⁺ cells Method II
1	pYearg4	3	
2	pYearg4	2	3
3	pYearg4	2	0
4	pYearg4	1	0
5	pYearg4	4	0
7	pYearg4	4	0
8	pYearg4	3	2
9	pBR322-arg4	1	0

Methods I and II refer to the poly-L-ornsthine and PEG transformation methods (see Fig. 1 legend). For each transformation 2×10^7 cells of cw15 arg7B were used. Cell survival was 50-80% in method I and 0-40% in method II. The pBR322-arg4 plasmid is described in Fig. 2 legend. In all cases 50 μg of salmon sperm DNA were included. In control experiments in which plasmid DNA was omitted, no Arg+ cells were recovered. Transformants T2-5 and T8-3 used in this study were obtained in experiments 2 (method II) and 8 (method I) respectively. Approximately one-half of the Arg+ cells examined by the Southern blotting technique displayed fragments hybridizing to the yeast DNA.

Fig. 1 Analysis of transformant T2-5. Two methods of transformation were used. I: 2×10^7 cells of arg7 cw15B at a concentration of $< 2 \times 10^6$ cells per ml were centrifuged at 3,000g for 5 min, washed once in Tris-acetate-phosphate (TAP), 0.2 M mannitol¹² and resuspended in 0.95 ml TAP, 0.4 M mannitol. Five to ten µg of pYearg4 plasmid DNA3 were preincubated with 50 μg carrier salmon sperm DNA and poly-L-ornithine in 5 mM ZnSO₄15 for 1 h on ice before being added to the cells. The final poly-L-ornithine concentration was 10 µg ml-1 and incubation was for 30 min at room temperature. Cells were washed three times in 5 ml TAP, 0.4 M mannitol; resuspended in 10 ml TAP, 0.2 M mannitol, 50 µg ml⁻¹ arginine and placed on a shaker at 150 r.p.m. for 20 h under a light intensity of 3,000 lx. The cells were concentrated to 1 ml and 0.2 ml aliquots were mixed with 3 ml top agar (0.6% agar in TAP, 0.2 M mannitol)16 at 37 °C and poured on TAP plates (1.5% agar). Controls were treated identically except that the plasmid DNA was omitted. II: The second method is similar to the yeast transformation procedure¹⁷. After resuspension of the cells in 0.2 ml 10 mM CaCl₂ in TAP, 0.4 M mannitol, plasmid DNA (5-10 μg) and carrier DNA (20-50 μg) were added and the mixture was incubated at room temperature for 15 min. Two ml of 30% PEG-4000 in 10 mM Tris-HCl pH7.5, 10 mM CaCl₂ were added and the cells were incubated for 30 min at room temperature. The cells were washed and plated as in method I. The nuclear DNA was isolated from a 500 ml stationary phase culture. Cells were washed once with TAP growth medium¹² and resuspended in 0.1 M NaCl, 20 mM Tris-HCl pH8.0, 50 mM EDTA. SDS and pronase were added at a final concentration of 1% and 500 µg ml-1 respectively. Fresh pronase was added after 45 and 90 min. After 2.5 h incubation at 50 °C the lysate was cooled and extracted with distilled phenol. The aqueous phase was precipitated with 2 vol ethanol and centrifuged for 10 min at 10,000g. The pellet was washed once with 70%

ethanol, dried and resuspended in 2 ml 10 mM Tris-HCl pH8.0, 1 mM

EDTA overnight. The preparation was then treated with 50 μg ml⁻¹ pancreatic RNAse for 1 h at 37 °C. The DNA was centrifuged in an ethidium bromide density gradient (Beckman Ti50 rotor, 50 h at 35,000 r.p.m.) after inactivation of the enzyme with 0.05% diethyl pyrocarbonate for 5 min at room temperature. The DNA band was removed with a pipette, extracted twice with isoamylalcohol, precipitated with 3 vol 70% ethanol, rinsed in 70% ethanol and resuspended in 10 mM Tris-HCl pH 8.0, 1 mM EDTA. The agarose gel electrophoretic patterns are a, DNA of transformant T2-5 digested with EcoRI; c, T2-5 DNA without digestion; e, DNA from non-transformed cells digested with EcoRI; g, DNA from non-transformed cells mixed with pYearg4 DNA digested with EcoRI. The DNA fragments were blotted onto nitrocellulose filters¹³. b, d, f, h Represent autoradiographs of hybridizations of the DNAs shown in a, c, e, g respectively, using nick-translated¹⁸ pYearg4 plasmid DNA as a probe. The discrete bands in a, e and g represent chloroplast EcoRI fragments and the band in c, ~15 kb, is mitochondrial DNA^{19,20}, Numbers on the left indicate the sizes of the fragments in kb. Hybridizations were performed as described previously²¹ with minor modifications. Nitrocellulose filters carrying DNA fragments (16 × 16 cm) were prehybridized in 6 × SSC (1 × SSC = 0.15 M NaCl, 0.015 M Na citrate pH 7.0), 1 mM EDTA, 0.1% SDS, 0.2% Ficoll, 0.2% polyvinylpyrrolidone, 0.2% bovine serum albumin, 50 μg ml⁻¹ salmon sperm DNA at 68 °C for 2-4 h. Hybridizations were in the same medium at 68 °C for 16-20 h except that the salmon sperm DNA concentration was raised to 1 mg ml⁻¹; 3 × 10⁶ c.p.m. of ³²P-labelled hybridization probe were added. Filters were washed twice in 2 × SSC, 0.1% SDS at room temperature; four times for 1 h in 0.1 × SSC, 0.1% SDS at 52 °C; and 10 min in 3 mM Tris-base at room temperature. Filters were dried and exposed to Kodak Xs-5 films with tungsten intensifyin

Comparison of the sizes of the *HindIII* fragments of pYearg4 (Fig. 2h) with the hybridization patterns obtained with the *HindIII* digests of the DNAs from the transformants T8-3 (Fig. 2c) and T2-5 (Fig. 2f, g) confirms that a deletion exists in the integrated plasmid DNA relative to the free plasmid. As no hybridization occurs at the position of fragment B which contains the arg4 locus, we conclude that a portion of this fragment has been fused to a nuclear DNA fragment. The fate of the smaller *HindIII* fragments of pYearg4 is more difficult to follow in the integrated state because the hybridization signals obtained with the probe are at the limit of detection.

Table 2 shows that the two transformants examined grow much more slowly than the non-arginine-requiring strain cw15. It also shows that the specific activity of ASL in crude extracts of the cw15 strain was 0.14 µmol arginine per mg protein per h, considerably lower than the value reported for wild-type cells9. The activity of this enzyme is known to increase when the cells are grown in medium containing low concentrations of ammonium9; however, our cw15 strain and the transformants grow very poorly in these conditions and it was therefore necessary to use high concentrations of ammonium (400 mg l-1) which repress the activity of the enzyme8. In addition, the enzyme may be subjected to more proteolysis due to the fragility of the cw 15 mutant cells. Table 2 shows that the ASL activities in the transformants are close to 5% of the value obtained in the cw15 strain, and are at the limit of detection. The yeast enzyme appears therefore to have a low activity in C. reinhardii and/or be unstable in these cells. It is known, however, that C. reinhardii can sustain a normal growth rate even if the level of ASL is low. While examining the interallelic complementation of several mutants of the arg7 locus of C. reinhardii, Loppes and Matagne9 found one diploid with a normal growth rate although the specific activity of ASL was only 5% of wild type. Besides interallelic complementation, it is also known that hybrid ASL can be formed between the products of wild-type and certain arg7 mutant genes14. The question arises whether the ASL enzyme of the transformants consists uniquely of yeast subunits

or whether it is made functional by the interaction of the yeast and mutated *C. reinhardii* subunits. Analysis of the heat sensitivity of the enzyme may distinguish between these two possibilities¹⁴, but we have not yet been able to perform such an experiment because of the low specific activity of the ASL enzyme in the transformants.

The stability of the transformants was examined by growing them for several generations in the presence of arginine. After 70 generations without selective pressure cells of T2-5 were still arginine independent. However, analysis of the integrated DNA by Southern blotting revealed changes in the hybridization pattern (Fig. 2). After 70 generations the EcoRI (compare Fig. 2d, e) and HindIII (compare Fig. 2f, g) fragments hybridizing to the probe have become smaller, suggesting that a segment of the integrated DNA has been deleted or that there has been a slight sequence rearrangement.

Because the transformation yield is still low it has been difficult to optimize the transformation procedure. It is not yet clear whether the limiting step is at the level of entry of DNA into the cells or at the level of stable integration of the DNA into the nuclear genome. Although the pYearg4 plasmid has been shown to contain a yeast replication origin and to generate high-frequency transformants in yeast⁴, we have no solid evidence that this replication origin is active in *C. reinhardii*. Note,

Table 2 Properties of transformants

Specific activity of ASL (µmol arginine per mg protein per h)	Generation time
_	14
0.14	7
0.01	17
0.01	23
	of ASL (µmol arginine per mg protein per h) 0.14 0.01

The specific activities of ASL in crude extracts were determined as described in ref. 8. Cells were grown in Tris-acetate-phosphate (TAP) medium except cw15 arg7 cells which were grown in TAP medium containing 50 μ g ml⁻¹ arginine.

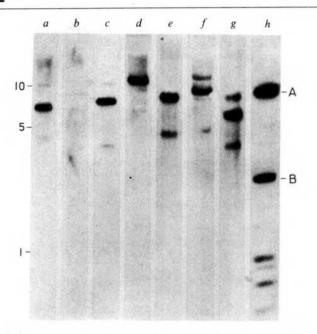

Fig. 2 Analysis of transformants. Preparation of the DNA of the transformants and the hybridizations of the DNA fragments with ³²P-labelled probes were performed as described in Fig. 1 legend. To obtain more specific hybridization to the arg4 region, the HindIII fragment containing arg4 (fragment B in lane h) was subcloned into pBR322. The new plasmid pBR322-arg4 was nick-translated and used as probe in the hybridizations shown in a-c, e, g. The hybridization probe used in d, f and h was pYearg4. Lanes a, b, c represent autoradiographs of hybridizations of the probe to DNA of the transformant T8-3: a, EcoRI digest; b, undigested DNA; c, HindIII digest. Lanes, d, f display hybridization patterns obtained with the DNA of T2-5 digested with EcoRI and HindIII respectively. Lanes e, g represent similar hybridizations with EcoRI and HindIII digests except that the DNA was extracted from T2-5 cells about 70 generations later than in d and f. Lane h displays the HindIII fragments of pYearg4. Fragments A and B contain the ColE1 vector and the yeast arg4 locus respectively3. Numbers on the left indicate the sizes of the fragments in kb

however, that two putative slow growing transformants were shown initially, by the Southern blotting technique (data not shown), to harbour non-integrated DNA molecules hybridizing with the pYearg4 plasmid. After further growth of these clones subsequent analysis failed to show any DNA fragment hybridizing to the probe. It is possible that the strains initially carried an autonomously replicating plasmid, which was lost after reversion to arginine independence.

Despite these uncertainties the experiments described here clearly show that transformation is feasible in C. reinhardii and that some of these transformants can be stably propagated. It will be important to develop suitable transformation vectors for C. reinhardii in order to allow transformation to become an efficient method for isolating nuclear genes by complementation of appropriate mutants and for studying the regulation of expression of nuclear genes of C. reinhardii and other plants.

We thank M. Chandler for helpful comments, O. Jenni for photography, and Dr J. Carbon for plasmid pYearg4. This work was supported by grant 3.659.0.80 from the Swiss National Foundation.

In vitro transformation of plant protoplasts with Ti-plasmid DNA

F. A. Krens, L. Molendijk, G. J. Wullems & R. A. Schilperoort

Department of Biochemistry, State University of Leiden, Wassenaarseweg 64, 2333 AL Leiden, The Netherlands

Genetic engineering requires a procedure for introducing DNA into host cells, followed by integration into the host genome and gene expression. Although several procedures for DNA-mediated gene transfer in mammalian cells, yeast and bacteria have been reported, no such methods are yet available for plant cells. The major obstacle to DNA uptake in plant cells is the cell wall, but this can be circumvented by using plant protoplasts, cells freed of their cell walls by enzymatic digestion. However, none of the reports on the uptake of DNA into plant protoplasts 1,2 has produced conclusive evidence for the integration of DNA into the host genome, that is, that stable transformation occurs. The tumour-inducing bacterium Agrobacterium tumefaciens, which causes crown gall disease, is a natural system for the introduction of foreign DNA into plants. This bacterium introduces part of its tumour-inducing (Ti) plasmid, called T-DNA, into plant cells, where it becomes integrated into the nuclear DNA of the host3 and is transcribed into mRNA5.6. T-DNA encodes tumourspecific enzymes responsible for the formation of amino acid derivatives such as octopine or nopaline7, which the bacterium can use as a sole source of carbon and nitrogen. The transformed cells have also acquired the ability to grow in the absence of phytohormones (autotrophy). An in vitro system for infection of Nicotiana tabacum protoplasts by A. tumefaciens has already been reported. Transformants are selected by their ability to divide and grow in tissue culture without the addition of plant phytohormones to the synthetic culture medium. Here, we report a reproducible method for the stable transformation of tobacco protoplasts with Ti-plasmid DNA, using a similar selection procedure.

Protoplasts, isolated from leaves of aseptically grown N. tabacum SR₁ shoots, were cultured in K₃ medium supplemented

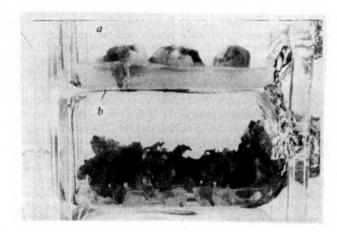

Fig. 1 Two callus lines obtained after in vitro DNA transformation growing in tissue culture on hormone-free LS medium. a, A typical non-regenerating line containing LpDH activity; pT2-15. b, A typical line that regenerates shoots, but lacks LpDH activity; pT2-6.

with phytohormones⁸ (see Table 1 legend). Normally, they form a new cell wall, divide and generate cell colonies (calli) which will eventually give rise to shoot-regenerating calli. In the present study transformants were selected on the basis of their phytohormone-independent growth. Other markers for the identification of transformants are the presence of lysopine dehydrogenase (LpDH) activity and T-DNA. Lysopine de-

N. tabacum SR₁ protoplasts (pps) were isolated from sterile shoots and suspended in K_3 medium containing 0.4 M sucrose, supplemented with naphthaleneacetic acid (0.1 mg I^{-1}) and kinetin (0.2 mg I^{-1}) at a density of $5 \times$ 105 pps per ml (ref. 8). (All conditions used in the isolation of pps and the culture of SR, shoots are described in ref. 8.) Fractions (1 ml, that is, 5×10^5 pps) were taken and 0.5 ml of polyethylene glycol (PEG 6000, 40% w/v) dissolved in a fusion medium11 (F) containing 140 mM NaCl, 5 mM KCl, 0.75 mM Na2HPO4, 5 mM glucose and 125 mM CaCl₂·2H₂O pH 7.0 was added, followed by 10 µg of pTiAch5 DNA (0.4 mg ml⁻¹) and 50 µg of CT-DNA (1 mg ml⁻¹). Massive clumping of the protoplasts occurred. Protoplasts were incubated at 26 °C for 30 min with occasional shaking, after which 10 ml F-medium was added stepwise in 2-ml portions at 5-min intervals. Aggregates broke up during this post-incubation. The protoplasts were pelleted by centrifugation and the supernatant was removed. The pellet was resuspended in 10 ml of K_3 medium and plated in 10-cm Petri dishes after addition of carbenicillin ($250 \mu g \text{ ml}^{-1}$). They were kept in the dark for 24 hand from then on in 2,000 lx for 12 h per day. Cell survival was $\ge 50\%$. Two weeks later, 5 ml of fresh K_3 medium was added. If the cell colonies were of sufficient size, they were plated in K3 medium containing 0.3 M sucrose solidified with 0.3% agar and still supplemented with phytohormones. After ~1 month on this medium the small calli were placed for selection on hormone-free K3 medium containing 0.2 M sucrose and 0.5% agar. Calli still growing after one or two passages on this medium were placed on hormone-free LS medium. At this stage transformants were detected and tested for LpDH activity. pT₂ and pT₇ represent the only two independent experiments that have been performed with the described procedure, and both showed a positive result. Other conditions that were tested but gave negative results differed in incubation time, a lower Ca²⁺ concentration in the post-incubation, and plasmid DNA concentrations (1-50 µg) in the presence and absence of CT-DNA as a carrier. Other procedures were also used, including the poly-L-ornithine method and Ca2+ phosphate-DNA co-precipitation method, which in our hands gave negative results

* These cell lines initially contained LpDH activity, but lost it after 2 months of subculturing.

hydrogenase synthesizes octopine and related compounds such as lysopine in tumour cells induced by an *A. tumefaciens* strain carrying an octopine Ti-plasmid.

The present transformation experiments used octopine Tiplasmid DNA from the wild-type strain Ach5(LBA4001). Plasmid DNA was dissolved at an appropriate concentration in sterile H₂O and its integrity and *SmaI* restriction pattern were checked by agarose gel electrophoresis. The DNA was stored in a sterile Eppendorf tube to which an equal volume of chloroform was added to kill any contaminants. The DNA was kept at 4 °C until use.

The transformation procedure involved incubating protoplasts and DNA in the presence of polyethylene glycol (PEG) and a post-incubation with high Ca2+ concentration (for details see Table 1 legend). This procedure is similar to one used in our laboratory for fusion of protoplasts to produce somatic hybrids. We first determined which PEG concentration would give sufficient cell survival (>20%) and negligible cell fusion during a 30-min incubation. In fusion conditions, PEG is usually present at a 40% concentration for several seconds. In the present experiments we found that a PEG concentration of 13.3% was optimal for an incubation of 30 min; cell survival was 50% and fusion <5%. In our initial DNA transformation experiments we determined whether it was best to start the post-incubation either with a one-step dilution of the PEG by adding 10 ml post-incubation mix containing 125 mM Ca2+ or gradually to dilute the PEG concentration stepwise while increasing the Ca2+ concentration, as is done in fusion experiments. We also examined whether the transformation was dependent on the concentration of Ti-plasmid DNA and the presence of 50 µg calf thymus (CT) DNA as a carrier. Out of 16 experiments, using different conditions, transformants were only found if 10 µg of Ti-plasmid DNA and 50 µg CT-DNA were used during the incubation and if the post-incubation mix was added stepwise. This procedure was tested twice (and both times gave rise to transformants) and Table 1 lists the transformed tissue lines obtained by this procedure in the two independent experiments. No phytohormone-independent calli were obtained in control experiments in which protoplasts were either incubated with CT-DNA alone or without addition of DNA.

From the first successful experiment (plasmid transformation $2=pT_2$), six tissue lines were obtained that showed both phytohormone-independent growth and LpDH activity, but no shoot regeneration. Five other lines proliferated without hormones but had no detectable LpDH activity (Fig. 1). These lines all had the capacity to regenerate shoots; two of them had initially shown the presence of the T-DNA coded enzyme, but had lost enzyme activity after 2 months of subculturing. When shoots that developed from these calli were placed on culture medium, they showed the same properties as regenerants obtained from

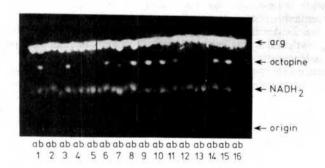

Fig. 3 Electropherogram of the products formed by LpDH activity in tissue extracts. The assay was performed as described by Otten¹². The reaction mixtures contained the extracts of the tissue lines listed in Table 1. a, Channels, reaction mixtures at t=60 min; 1, B6S3 crown gall tumour callus (positive control); 2–13, pT₂ nos 2, 3, 6, 8, 9, 10, 11, 13, 14, 15, 20 and 21, respectively; 14, 15, pT₇ nos 2 and 3; 16, SR₁ shoot (negative control).

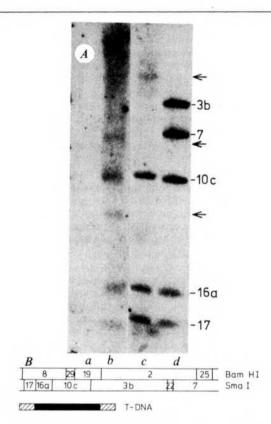

Fig. 4 A, detection of T-DNA in DNA transformed tissue line. The plant DNA was isolated as described by Heyn et al. 13 and as modified by Chilton et al.14. The DNA was digested with the restriction endonuclease SmaI and ar. The DNA was agested with the restriction endouclease Smal and fractionated by agarose (0.7%) gel electrophoresis¹⁰. Blots were prepared according to the procedure of Southern¹⁵ and hybridization was carried out as described by Thomashow¹⁶. A mixture of two recombinant DNA plasmids was used as DNA probe. They consisted of pBR322 in which BamHI fragment 8 (pAL3252) and BamHI fragment 29, 19, 2 and 25 (pAL3076) of the octopine Ti-plasmid were cloned, respectively. The plasmids were separately labelled *in vitro* with ³²P by nick translation¹⁷. The autoradiogram shows the hybridization of the probe to that of the plant DNA. Lane a, SR, (control); lane b, transformant pT₂-13; lane c, transformant pT₂-14; lane d, a one-copy reconstruction of the Ti-plasmid¹⁰. The arrows indicate the border fragments of the T-DNA in the transformants. B, a physical map of a portion of octopine Ti-plasmids representing the restriction endonuclease fragments of BamHI and Smal. The filled bar in the lower part of this figure shows the T-DNA organization as it is found in octopine crown gall tissues

bacterial transformation experiments, that is, an inability to form roots and the absence of apical dominance, resulting in the development of shoots from lateral buds9. Several regenerants were grafted onto stems of N. tabacum var. Samson. Flowers of the mature, grafted shoots possessed an extended stamen and were male-sterile, as was observed previously for transformants9 obtained after bacterial infections of protoplasts (Fig. 2). Another line lost the ability for hormone-independent growth and is now being cultured on medium containing naphthaleneacetic acid and kinetin. It still had LpDH activity. A second independent experiment (PT7) gave rise to two phytohormone-independent, non-regenerating tissue lines with LpDH activity. From the 14 transformed tissue lines obtained in two separate experiments, 11 have been stable from the beginning with regard to their phenotypic properties. The three lines which changed in phenotype have now been stable for at least 9 months. We do not know the reason for the variability in both number of transformants and their phenotype between the two experiments. The transformation event itself, using this procedure, is reproducible, but the transformation frequency and phenotypic diversity apparently differ between experiments. Figure 3 shows the result of the assay for LpDH activity in the various tissue lines.

As further evidence for the transformed nature of the tissues obtained, we have demonstrated the presence of Ti-plasmid

DNA sequences. DNA isolated from two tissue lines (phytohormone independent, LpDH⁺) was digested with the restriction endonuclease SmaI and fractionated by agarose gel electrophoresis. Southern blots were prepared from the gels and hybridized with in vitro labelled DNA probe. Figure 4 gives the results of hybridization for two lines, and shows the contiguous Smal fragments 16a and 10c, which are always found in octopine tumour tissues and which are believed to carry sequences essential for the maintenance of the transformed state of the callus¹⁰; a band corresponding to SmaI fragment 17 is also present, located to the left of 16a; this has only been found in one cell line obtained at our laboratory by in vivo infection. Although both tissue lines analysed contain the same internal Smal fragments, we conclude from the difference in border fragments in which plant DNA and bacterial DNA are joined (indicated by arrows in Fig. 4) that the two lines arose from independent transformation events within one experiment. The presence of Smal fragment 17 in DNA transformants may indicate that frequently a larger part of Ti-plasmid is integrated into the host genome than on infection with the bacterium. Confirmation of this awaits further T-DNA analysis of other transformed tissue lines.

The larger extent of T-DNA in DNA transformants might indicate that the transformation of protoplasts is not due to an A. tumefaciens infection. The following arguments make the possibility of an infection leading to transformation unlikely. The experiments are performed in stringent aseptic conditions. The most conspicuous source of infection would be the plasmid DNA itself if bacteria had survived the isolation procedure. For this reason, the DNA was sterilized with chloroform and sterility was checked by plating a drop of the DNA solution on tryptoneyeast medium. No colonies were formed after 3 days at 29 °C. Moreover, in our experience, in vitro transformation with A. tumefaciens only occurs in certain conditions (F. A. Krens et al., in preparation): the protoplasts must be 3 days old, the incubation time must be >24 h and the density of the bacteria must be at least 3×10^5 per 10^5 protoplasts. None of these conditions is met in the procedure for DNA transformation.

The present results indicate that we have developed a reproducible method for the stable transformation of plant protoplasts with Ti-plasmid DNA. This, for the first time, conclusively demonstrates that the Ti-plasmid is the tumourinducing principle and that A. tumefaciens itself is not a prerequisite for obtaining tumour cells. DNA transformation experiments may aid in elucidating the molecular basis of crown gall tumorigenesis. Experiments have already been started using mutated Ti-plasmids carrying insertions that lead to avirulence of the mutants in vivo. The evidence presented here that plant cells can be stably transformed with DNA will undoubtedly also stimulate programmes for genetic engineering in higher plants.

A viral polymerase involved in recognition of influenza virus-infected cells by a cytotoxic T-cell clone

J. R. Bennink*, J. W. Yewdell† & W. Gerhard†

* Basel Institute for Immunology, CH-4005 Basel, Switzerland † The Wistar Institute of Anatomy and Biology, 36th Street at Spruce, Philadelphia, Pennsylvania 19104, USA

Influenza virus-specific cytotoxic T lymphocyte (CTLs) can be obtained from mice and humans infected with influenza A viruses^{1,2} and appear to be beneficial in the host response³. The viral target structure recognized by influenza virus-specific CTLs remains a controversial question for two reasons: first, previous specificity analyses were difficult to interpret because of heterogeneous CTL populations, and second, more than one viral protein has been detected serologically on the surface of influenza-infected cells⁴⁻¹⁰. To avoid these problems, antiinfluenza A/PR/8/34 CTL clones were generated and tested for cytolytic activity on target cells infected with recombinant viruses containing known rearrangements of the genes of strains A/PR/8/34 and A/HK/1/68. We report here that one such CTL line lysed target cells only if the infecting virus possessed the polymerase gene P3 of A/PR/8/34. This suggests that the P3 gene product either induces a virus-specific cell-surface antigenic modification or is expressed on the surface of the infected cell, and hence is involved in recognition of target cells by the anti-influenza CTL line.

Influenza type A-specific CTLs were generated as described elsewhere 11,12. BALB/c mice were inoculated intraperitoneally (i.p.) with A/PR/8/34; 2-4 weeks later, the primed spleen cells were cultured in vitro for 10 days in the presence of PR8infected BALB/c spleen cells. Our method differs from the standard technique in that the culture from which the CTL line described here (BCIP3.1) was derived was then treated with monoclonal anti-Lyt 2 antibody 3-168.8 (ref. 13) (the gift of F. Fitch, University of Chicago) plus complement. Initially this treatment was performed to enrich for helper T cells. Although the percentage of Lyt 2⁺ cells was reduced at the time of treatment to less than 1% (as shown by immunofluorescence), most of the cultures retained antiviral CTL activity and ~5-10% were 'strain-specific'. CTL clones derived from these cultures have subsequently been shown to be Lyt 2+ by immunofluorescence. 'Cross-reactive' CTL lines alone were isolated from cultures not treated with anti-Lyt 2 antibodies. All cultures were propagated in vitro in medium containing 20% supernatant from concanavalin A (Con A)-stimulated rat spleen cell cultures and, after 2-3 months, cloned on a feeder layer of irradiated BALB/c peritoneal exudate cells. The CTL line BCIP3.1 described here has been maintained in culture for 6

The specificity of the BCIP3.1 line was examined in microcytotoxicity assays on P815 cells infected with various influenza viruses. As shown in Table 1, the cytotoxic activity was restricted to cells infected with influenza viruses A/Swine/31 (A/SW/31), A/Puerto Rico/8/34 (A/PR/8/34), A/Melbourne/35 (A/Mel/35) and A/BH/35. The failure of BCIP3.1 to lyse target cells infected with the other influenza A viruses was not due to inadequate expression of viral antigens on these target cells as they were killed by one or several other CTL lines included as positive controls (J.R.B., in preparation).

As the BCIP3.1 clone lysed cells infected with A/Puerto Rico/8/34 (PR8) but not with A/Hong Kong/1/68 (HK) (Table 1), it was possible to examine its specificity further using target cells infected with recombinant viruses containing various

arrangements of parental PR8 and HK genes. Due to the segmented genome of influenza viruses, such recombinant viruses can be readily produced by mixed infection, and their genotype determined by RNA-gel electrophoresis¹⁴. Thus, the BCIP3.1 line was tested for cytotoxic activity against P815 cells infected with 17 different PR8-HK recombinant viruses of defined genotypes (gifts of Drs P. Palese, J. Schulman and M. Lubeck, Mt Sinai School of Medicine). It can be seen from the top half of Table 2 that the BCIP3.1 clone does not lyse targets infected with 10 recombinant viruses which lack the PR8 P3 gene. Particularly striking is the recombinant E61-24-P15 which differs from PR8 solely in the substitution of the P3 gene. This absence of cytotoxicity is due neither to the failure of these viruses to infect the target cells, nor to a general resistance of the infected cells to lysis by CTLs, as the cells were lysed to the same extent as PR8-infected cells by cloned CTL lines specific for other viral target structures (J.R.B., in preparation). In contrast, the bottom half of Table 2 shows that target cells infected with recombinant viruses having the PR8 P3 gene were lysed. As PR8 P3 is the only gene in the recombinant virus panel which correlates absolutely with the presence or absence of cytotoxic activity, we conclude that the BCIP3.1 T-cell clone recognizes a target structure on P815-infected cells which requires the presence of the PR8-derived P3 gene.

However, lysis of recombinant virus-infected target cells by the BCIP3.1 clone is not a simple all-or-none phenomenon because the extent of lysis seems to be affected to some extent by additional genes: for example, the highest ⁵¹Cr release (45–60%) was observed for the four recombinants E61-24-H16, J1, 13B and J5 which have in common the PR8-derived genes P3 (prerequisite for lysis), P2 and Np. However, substitution of either the P2 or nucleoprotein (NP) genes of PR8 by the corresponding HK genes resulted consistently in reduced ⁵¹Cr

Table 1 Cytotoxic activity of BCIP3.1 CTL line on P815 cells infected with various influenza virus strains

Type A influenza viruses have been grouped into three subtypes designated H1N1, H2N2 and H3N2. H1, H2 and H3, and N1, N2 each designate serologically non-cross-reactive serotypes of the haemagglutinin (HA) and neuraminidase (NA) molecules, respectively. Each subtype consists of many distinct but antigenically related glycoproteins that characterize individual virus strains. Infectious allantoic fluid of these viruses was used to infect P815 cells as described previously Six hours after infection, cells were incubated for 1 h with ⁵¹Cr at 37 °C washed twice and then dispensed into wells of microtitre plates (104 cells per well). BCIP3.1 cell ratio of 9:1. The cells were pelleted lightly and after 4 h incubation at 37 °C, one-half of the culture supernatant was removed for determination of the concentration of released by y counting. Per cent specific release was determined according to the equation: experimental release (in the presence of CTLs)spontaneous release (no CTLs)/total release (in the presence of detergent)-spontaneous release. Each assay was 'performed in triplicate.

release, that is, 23-26% and 13% for recombinants E61-13-H17, E61-13-H20 and E61-13-H19 respectively.

The frequency of CTLs possessing the BCIP3.1 specificity in the influenza immune response is unknown. Previous frequency analyses could have placed this specificity with either 'strainspecific' or 'cross-reactive' CTLs, depending on the viruses tested. The finding of at least two other clones, one having an apparently identical specificity and another with a slightly different specificity but correlating with the polymerase gene complex (unpublished data) suggests that the BCIP3.1 is not an unusual clone. The role and relative importance of the polymerase gene complex in the CTL immune response are unknown.

The association of the lytic activity of BCIP3.1 with the presence of the PR8 P3 gene can be explained by two mechanisms. First, BCIP3.1 could recognize the P3 protein itself. Although P3 is present in infected cells in only small quantities compared with the other viral proteins, and appears to be located predominantly in the nucleus and cytoplasm 13,16, it remains a possible target structure, as the amount of viral antigen needed for lysis by CTLs is unknown and the possible presence of small amounts of cell-surface-associated P3 has not been investigated. Alternatively, P3 may be required for the expression of the target structure recognized by BCIP3.1. In this respect, note that the function of the P3 protein in influenza virus infection is incompletely understood. Results obtained for temperature-sensitive mutants indicate a role for P3 in complementary (messenger) RNA synthesis¹⁷, and suggest that P3 is involved in the transport of the viral transcription-replication complex (consisting of the P1, P2, P3 and NP proteins¹⁶) from nucleus to cytoplasm¹⁸. Thus the PR8 P3 protein may modify another viral (or cellular) gene product recognized by the BCIP3.1 line, or may be responsible for transport of this antigen to the cell surface. The finding that the cytotoxic activity of BCIP3.1 is also related to the presence of two other proteins (P2 and NP) known to be involved in the virus transcriptionreplication complex, does not help to distinguish between these possibilities as this observation could reflect either the involvement of P2 and NP in the surface expression of P3 or the higher efficiency of a PR8 P2-P3-NP complex in the expression of the actual antigen recognized by BCIP3.1.

⁵¹Cr-release assays were performed on P815 cells 7 h after infection with recombinant viruses containing various combinations of PR8 (P) and HK (H) genes coding for the three viral polymerases (P1, P2 and P3), haemagglutinin (HA), neuraminidase (NA), nucleoprotein (NP), matrix (M) and non-structural (NS) proteins. The pooled data from three separate cytotoxicity assays are shown.

In conclusion, we have demonstrated that the PR8 P3 gene product, perhaps in association with other viral gene products, is involved in the recognition of target cells by an anti-influenza CTL line. However, it remains to be determined how P3 affects the target cell surface and whether it plays an important part in the recognition of influenza-infected target cells by CTLs.

We thank S. Fazekas de St Groth and F. Melchers for their critical reading of the manuscript and L. Forni for the Lyt 2 immunofluorescence testing. Monoclonal antibody to Lyt 2 antigen blocks H-2I- and H-2Kspecific mouse cytotoxic T cells

Richard A. Miller & Osias Stutman

Memorial Sloan Kettering Cancer Center, New York, New York 10021, USA

It has been proposed that the murine cell surface antigen Lyt 2 could serve to distinguish cytotoxic T lymphocytes (CTLs) and their immediate precursors, which bear Lyt 2, from helper T cells, which do not1. Later work, however, has demonstrated that Lyt 2+ cells can 'help' B cells mature into antibody-secreting cells, provided that the B cells differ from the allo-helper T cells at the K or D region of the H-2 major histocompatibility complex (MHC)2. Furthermore, a T-cell line has recently been described which is Lyt 2⁻ but specifically cytotoxic for *H-21* region determinants^{3,4}. These new findings have prompted an alternative hypothesis, that Lyt 2 antigen does not discriminate between cytotoxic and non-cytotoxic (helper) T cells, but rather between I-region- and K/D-region-specific cells⁵. In this new view, the apparent association between presence of Lyt 2 antigen and killer T-cell function merely reflects the tendency, by no means absolute 6-8, for CTLs to recognize K- or D- rather than I-region determinants⁹. We show here that I-regionspecific murine CTLs, generated in primary in vitro culture, do in fact bear the Lyt 2 antigen, as do CTLs directed against the K region of H-2.

Our method is based on the observation that the lytic reaction between mouse CTL effectors and their targets can be blocked by addition of anti-Lyt 2 antibody directly to the cytotoxicity assay¹⁰⁻¹³. Although it is not clear how the antibody interferes with target cell lysis, the finding that inhibition does not require Lyt 2 expression by the target cells strongly suggests that recognition of the Lyt 2 molecules on the CTL effector cell is

Spleen cells from unprimed responder mice were mixed with irradiated (1,500 rad) stimulator spleen cells, and cultured in conical-bottomed microtitre wells such that each well contained 3×10^5 responder cells and 5×10^5 stimulators in 0.2 ml of RPMI-1640 medium with 10% fetal calf serum, 10 mM HEPES, antibiotics and added glutamine. After 5 day culture at 37 °C, the medium was shaken off and the cell pellet resuspended in 0.1 ml of serum-supplemented medium containing the antibody to be tested for inhibitory effect. Another 0.1 ml of medium was then added containing 2×10^4 51Cr-labelled concanavalin A-stimulated spleen cells of the indicated strain, as targets. After a 4 h incubation at 37 °C, the plates were centrifuged at 1,000 r.p m for 10 min and 0.1 ml of supernatant was removed for counting Per cent specific lysis was calculated as $100 \times (\text{experimental} - \text{low control})/(\text{acid lysis} - \text{low control})$. Six to elght statistically independent replicates were performed for each experimental condition tested; the equivalent ratio of viable effector cells to targets is $\sim 10:1$. Anti-Lyt 2 is hybridoma clone 53-6.7 of ref. 15, used at 1/100 in expt A, and 1/500 in expts B and C. Normal nude mouse serum (nude NMS) and anti-Lyt 1 antibody (clone 53-7.3) were used at 1/500 Ascites fluid containing mouse monoclonal antibody to Lyt 2.2 was used at 1/100. Strain abbreviations and genotypes are as follows: AQR, B10.AQR($K^4I^{k/d}D^d$); T6R, B10.T(6R) ($K^4I^{k/d}D^d$); A, B10.A($K^kI^{k/d}D^d$). All three strains are TD^a

involved^{10,11}. Cytotoxicity can be blocked by conventional alloantisera and by monoclonal antibodies specific for the Lyt 2 molecule^{10–13}.

To examine I-region-specific CTL responses of unprimed mice, which have been reported to be considerably weaker than the in vitro responses obtained from in vivo immunized responders6, we performed the 5 day in vitro sensitization culture and the 4 h 51Cr-release assay for cytotoxicity in conical-bottomed microtitre wells, which we have found produce satisfactory responses to several 'weak' antigens (that is, non-H-2 determinants). To generate I-region immune CTL effectors, we carried out reciprocal in vitro sensitizations between congeneicresistant mouse strains B10.AQR and B10.T(6R), which differ only at the I region of the MHC14. B10.A stimulators, which differ from B10.AQR only at the K region, were used to produce K-specific CTLs as a positive control. At the end of the 5 day sensitization period, the CTL assay was carried out in the presence of either monoclonal antibody to Lyt 2 or control serum. A monoclonal rat antibody to a nonpolymorphic portion of the murine Lyt 2 molecule was used (clone 53-6.7 of ref. 15), and we found that this antiserum inhibits both I- and K-regionspecific CTL reactions at dilutions >1/3,200.

Table 1 shows the results of three consecutive experiments; the monoclonal antibody to Lyt 2 not only blocks K-specific CTLs as expected, but also interferes with I-region-specific CTLs, and to the same extent. CTLs specific for Iq (Table 1, lines 2, 6, 12), I' (Table 1, lines 10, 20) and K' (Table 1, lines 4, 8, 18) are all strongly inhibited by the addition of anti-Lyt 2 antibody. The specificity controls show that the CTLs are in fact I-region specific (compare lines 11, 16 and 19, 21), as they kill only those targets which present the appropriate alloantigen; target cell death thus cannot be attributed to an antigen-nonspecific cytolytic event. Because the source of monoclonal antibody was serum from nude mice bearing the hybridoma as a subcutaneous tumour, controls were carried out (experiment C of Table 1) to show that the inhibitory activity was attributable to the anti-Lyt 2 antibody in the serum, rather than to some unsuspected material which might be present in sera from tumour-bearing nude mice. In studies involving conventional (non-monoclonal) antibodies of the Lyt type, the best control¹⁶ is to compare the

effect of the antibody on responder mice which differ only at the locus in question (here Lyt 2), but such a control is impossible in our study because it would require mice that are congeneic at both the Lyt 2 and I-region loci. Table 1 shows that neither normal nude mouse serum (Table 1, line 14) nor serum from nudes carrying a hybridoma (clone 53-7.3 of ref. 15), which secretes antibody to mouse Lyt 1 antigen (Table 1, line 15), was able to inhibit CTL effector activity, showing that the inhibitory activity of the anti-Lyt 2 hybridoma antiserum depended on the presence of antibodies to Lyt 2. Furthermore, line 13 in Table 1 shows that strong inhibition of cytotoxicity can also be obtained by a second monoclonal anti-Lyt 2 antiserum (provided by Dr U. Hammerling), which is specific for the polymorphic determinant Lyt 2.2 and is used as ascitic fluid from tumour-bearing mice. As inhibitory activity is found only in those sera from hybridoma-bearing nude mice which include anti-Lyt 2 antibody, and both monoclonal reagents (reactive with different determinants on the Lyt 2 molecule) exhibit potent blocking activity, we are confident that the inhibition seen results from an interaction between anti-Lyt 2 antibody and CTL surface Lyt 2 molecules. In summary, Table 1 shows that CTL activity against both I- and K-region antigenic determinants can be blocked by monoclonal anti-Lyt 2 antibodies, and that this blocking is attributable to the anti-Lyt 2 antibody in such reagents.

Although inhibition of lysis by anti-Lyt 2 antibody, as argued above ^{10,11}, need not involve Lyt 2-bearing target cells, we considered whether the inhibition shown in Table 1 might involve, not an interaction between the antibody and the CTL effectors, but rather a previously unknown protective effect of anti-Lyt 2 antibody on the concanavalin A blast targets, a portion of which exhibit Lyt 2 antigen¹². The experiment shown in Table 2, however, shows that strong inhibition of cytotoxicity by anti-Lyt 2 antibody is obtained even when the target cells are lipopolysaccharide activated B cells, selected by adherence to plastic plates coated with anti-mouse immunoglobulin; these cells do not carry surface Lyt 2. Thus, inhibition of *I*-region-specific CTLs can be induced by an interaction between anti-Lyt 2 antibody and the CTL effector cell itself.

It is not yet clear at what stage of cell-mediated cytotoxicity the Lyt 2-mediated blocking is achieved, although the

Experimental conditions were as for Table 1, except that the ⁵¹Cr-labelled targets were plate-selected ²⁶ B cells stimulated with lipopolysaccharide (5 µg ml⁻¹) for 48 h before use. All inhibitory antibodies were used at 1/300 dilution Per cent lysis is presented as mean (and s.e.m.) of 16 wells per group.

tantalizing proximity of the Lyt 2 gene to the mouse V_{κ} locus¹⁷, which controls the variable region of the κ light chain, and the demonstration¹³ that anti-Lyt 2 antibody blocks conjugate formation, but not lysis itself, suggest that inhibition of specific target recognition may be involved. In any case, our results indicate that however the Lyt 2-bearing molecules in the effector cells are involved in cytolysis, they are likely to have an equivalent role regardless of the genetic region—I or K/Dwhich controls the target cell antigens being recognized by the effector CTL. They also demonstrate, a fortiori, that I-specific CTLs induced by primary in vitro sensitization must be Lyt 2+ cells.

We cannot exclude the possibility that some I-specific CTLs produced from normal spleen cells might be Lyt 2-, and thus resemble the Lyt 2⁻, I-A^k-specific cytolytic T-cell line recently described^{3,4}, but we believe that most *I*-specific CTLs, like their more easily generated K/D-specific counterparts¹ and many cytolytic T-cell lines^{18,19}, are probably Lyt 2⁺, based on the unambiguous inhibition of cytotoxicity produced by the anti-Lyt 2 reagents in the present experiments. Our results are consistent with a recent study²⁰ showing that *I*-specific primary CTL effectors could be killed by sufficiently potent anti-Lyt 2 antisera and complement.

Generation of cytotoxic effector cells is now believed to involve collaboration between the CTL precursors and a 'helper' T cell which produces the helper factor interleukin-2 (IL-2)^{21,22}. Although K-region-stimulated secretion of IL-2 by Lyt 1⁻²⁺ cells has been reported recently^{23,24}, we have found²⁵ that positively selected Lyt 2+ cells produce much less IL-2, even in response to K-region disparities, than do I-regionstimulated Lyt 2 cells. We thus favour a model for CTL generation across MHC incompatibilities in which most of the IL-2-producing helper cells are I-region sensitive and Lyt 2 and most of the CTLs, whether K- or I-region responsive, are nonetheless Lyt 2+. The extent to which the allospecific CTLs resemble CTLs generated in vivo or to 'foreign' antigens in syngeneic contexts requires further investigation.

We thank Ms F. Lebow for technical help, Dr U. Hammerling for antibody, Dr C. David for mice, and Ms L. Stevenson and Ms M. King for preparing the manuscript. This work was supported by NIH grants AG-02497 and AG-02152. R.A.M. was a Special Fellow of the Leukemia Society of America.

Glycolipid affinity purification of migration inhibitory factor

David Y. Liu, John R. David & Heinz G. Remold

Department of Medicine, Harvard Medical School, and Department of Rheumatology and Immunology, Brigham and Women's Hospital, Boston, Massachusetts 02115, USA

Migration inhibitory factor (MIF) is an immune mediator secreted by primed lymphocytes on in vitro challenge by antigen or mitogen, which elicits various physiological responses from its target cell, the macrophage^{1,2}. Previous studies suggest that membrane glycoconjugates have an important role in regulating the interaction between MIF and the macrophage. A macrophage glycolipid functions as a putative receptor for MIF as evidenced by its ability to enhance the macrophage response to MIF^{3,4}. This enhancing ability of glycolipids requires the presence of sialic acid⁵ and fucose⁶; these carbohydrate residues are also required on the macrophage surface for the induction of an intact response by MIF5,7. Furthermore, it has been reported4 that incubating a preparation of mixed gangliosides from bovine brain with lymphocyte supernatants abolished their MIF and macrophage activating factor (MAF) activities. Taken together, these results are evidence that a glycolipid serves as a membrane receptor for MIF. We predict that glycolipids which enhance the macrophage response to MIF, also bind MIF with subsequent elution of biological activity, and present here evidence in support of this notion. We also demonstrate that glycolipid covalently bound to agarose provides a novel means of affinity purification of MIF.

Guinea pig⁸ and human⁹ MIF have been fractionated in this laboratory by various conventional techniques including gel filtration, electrophoresis and isoelectrofocusing. These procedures separate macromolecules on the basis of their physicochemical properties and thus are limited by their lack of specificity. Affinity chromatography is a useful technique for the purification of many proteins, and has been used successfully to purify MIF^{10,11}. Here we used an insoluble agarose support, derivatized with a macromolecular arm (poly-L-lysine¹²) followed by covalent attachment of gangliosides to this support¹³, to purify guinea pig MIF.

Results of initial purification experiments are shown in Fig. 1. MIF does not bind or is not adsorbed to columns containing unsubstituted agarose in the presence of phosphate-buffered saline (PBS) (0.15 M NaCl in 0.01 M phosphate-buffer pH 7.4). However, a substantial amount of MIF activity does adsorb to agarose covalently bound to a mixed preparation of bovine brain gangliosides. This adsorption appears to be specific as no adsorption occurs on agarose substituted with other preparations of glycolipids, for example, disialoganglioside (GD_{1a}), bovine brain grey matter and guinea pig brain (Fig. 1). Furthermore, the adsorbed MIF activity was recovered by elution with 0.2 M fucose in 1 M potassium thiocyanate (KSCN). Recovery of active MIF showed that use of ganglioside-agarose to purify MIF was possible.

In the experimental protocol described in Fig. 1 legend, a significant amount of protein (12-30%) eluted with MIF (data

Glycolipid preparations were tested for their ability to enhance the macrophage response to MIF, using methods described elsewhere³. Briefly, the test glycolipid deposited with lecithin and cholesterol as a thin film on a glass wall *in vacuo*. Liposomes were formed under nitrogen in buffer by agitation and sonication. After centrifugation the small liposomes were incubated with macrophages at 37 °C for 1 h. Cells were then washed and assayed for their response to a low dose of MIF in a capillary tube assay. The MIF response is shown as % inhibition of migration. The preparation of mixed gangliosides from bovine brain and glycolipids from guinea pig macrophages were the only preparations able to enhance the macrophage response to MIF.

not shown). Experiments were done to investigate whether different buffer conditions would remove unwanted protein from the eluent (Fig. 2). MIF was allowed to bind in a buffer of relatively high salt concentration (0.3 M NaCl in 0.01 M phosphate buffer pH 7.4 [0.3 M PBS]). The column was then washed with 0.6 M NaCl in 0.01 M phosphate buffer pH 7.4 (0.6 M PBS) and MIF eluted with 1.0 M KSCN in 0.01 M phosphate buffer pH 7.4 (1.0 M PBS). Most of the protein eluted before MIF (Fig. 2), thereby facilitating a significant increase in the specific activity of MIF (Table 2).

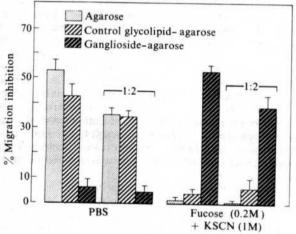

Fig. 1 Specific binding of MIF to ganglioside-agarose columns. Guinea pig MIF was prepared from culture supernatants of concanavalin A-stimulated lymph node cells from PPD-sensitized Hartley guinea pigs and chromatographed on Sephadex G-100 columns. One unit of MIF was defined as the greatest dilution giving 20% inhibition of migration in the capillary tube assay5. To determine the number of MIF units in a particular fraction, serial twofold dilutions were assayed. Sepharose 4B (Pharmacia) was activated by CNBr and coupled to poly-L-lysine (molecular weight 500,000; Sigma)12 Mixed gangliosides from bovine brain (Supelco) were coupled to poly-L-lysine-agarose using carbodiimide¹³. Approximately 80% of the Approximately 80% gangliosides were insolubilized as determined by the amount of free sphingosine in the reaction mixture. The coupled agarose was diluted fivefold with Sepharose 4B and packed in glass columns $(1 \times 10 \text{ cm})$ with a total bed volume of 3-4 ml. MIF $(16-20 \text{ units or } \sim 10 \text{ ml})$ equivalents of original supernatant) was percolated on to the column at room temperature with a flow rate not exceeding 10 ml h-1. The column was equilibrated and washed with PBS buffer followed by 0.2 M fucose in 1 M KSCN; 10 ml of each wash were collected on ice, vacuum-concentrated to 3 ml and dialysed overnight against minimal essential medium plus Earle's salts (Microbiological Associates). The equilibration and elution buffers and the types of agarose used are indicated. B represents unsubstituted agarose (poly-L-lysine-agarose without ganglioside);
represents agarose coupled to glycolipids prepared from bovine brain grey matter6, guinea pig whole brain6 or GD1a; represents agarose coupled to bovine brain mixed gangliosides (BGSL). Note that MIF activity (undiluted and 1:2 dilution) elutes through the control columns with the PBS wash and through the BGSL-agarose column only with the fucose-KSCN buffer. The differences between all six experiments were statistically significant (P < 0.001) by Student's t-test.

The results shown in Table 1 indicate a correlation between the reversible binding activity of a glycolipid preparation and its ability to enhance the macrophage response to MIF. We succeeded in enhancing MIF activity by preincubating macrophages with their putative glycolipid receptors for MIF as described previously⁶. The only glycolipid preparation to which MIF could be bound and recovered (mixed ganglioside from bovine brain) was also able to enhance the macrophage response to MIF—further evidence that gangliosides serve as MIF receptors.

As carbohydrate is known to be an essential part of the macrophage response to MIF⁵⁻⁷ we investigated the use of fucose as a specific eluent in a more effective purification method for MIF. Preliminary studies indicate that fucose alone is unable to elute MIF from ganglioside-agarose columns. KSCN alone was effective in the recovery of MIF, which is not surprising in view of what is known about carbohydrate-protein interactions. Simple monosaccharides, such as fucose, exhibit biological effects only at very high concentrations^{7,10,14}. In the case of ganglioside receptors, it appears that the specific oligosaccharide sequence and not just the presence of sialic acid is important for receptor function 15,16. It may be necessary to elute MIF with the oligosaccharide moiety of the putative glycolipid receptor. This could also explain why the ganglioside-agarose matrix is still effective for the purification of MIF even though the gangliosides are covalently bound to the polylysyl backbone

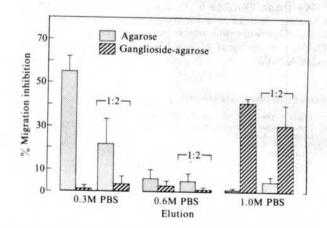

Fig. 2 Purification of MIF by salt elution from ganglioside-agarose columns. Partially purified MIF was subjected to affinity chromatography on ganglioside-agarose columns as described in Fig. 1 legend with the following modification. The equilibration and two sequential buffer elutions consisted of 0.01 M phosphate buffer pH 7.4 with 0.3 M NaCl, 0.6 M NaCl, and 1.0 M KSCN, respectively. represents unsubstituted agarose; ☑ represent agarose coupled to bovine brain mixed ganglioside. Note that MIF activity could be quantitatively recovered in the 1.0 M KSCN elution after binding in 0.3 M NaCl buffer. In three experiments, differences between each of the elutions were statistically significant (P < 0.001).

Table 2 Affinity purification of MIF on ganglioside-agarose

	Total protein (mg)	Total units	Specific activity (U mg ⁻¹)	Purification
Before purification	0.20	16	80	1
0.3 M	0.061	0	0	0
0.6 M	0.016	0	0	0
1.0 M	0.0017 (3%)	13.4 (84%)	1,914	24

The data summarize an experiment described in Fig. 2 legend. Percentage yield is given in parentheses. The breakthrough is represented by 0.3 M PBS, elution 1 is represented by 0.6 M PBS and elution 2, 1.0 M PBS. Purification may be more or less marked depending on the MIF preparation. One unit of MIF activity was defined as the highest dilution giving 20% inhibition of migration in the capillary tube assay.

through their sialic acid residues. MIF may recognize the oligosaccharide and not just sialic acid.

However, the method used here for coupling gangliosides to agarose does present the possibility that hydrophobic forces are involved in the ganglioside-MIF interaction, together with an affinity of MIF for carbohydrate residues. The dual nature of interactions between macromolecules has been shown previously for interferon¹⁴ and tetanus toxin¹⁷. Furthermore, the increasing ionic strengths of the buffers used in the protocol described in Fig. 2 legend may strengthen the hydrophobic interactions. This would result in a high binding affinity necessitating the use of chaotropic ions, such as thiocyanate in the case of MIF and serum growth factor¹⁸ or 7 M guanidine HCl in the case of cholera toxin¹³, which promote macromolecular unfolding and dissociation.

It is probable that only a minor unknown component of the bovine brain ganglioside mixture has a biospecific affinity for MIF⁴. We therefore have to consider the overlapping effects of other ganglioside-protein interactions which obscure the particular interaction in question. It might be better to examine an affinity adsorbent that contains only the homogeneous putative glycolipid receptor for MIF19

We have shown that gangliosides covalently bound to derivatized agarose provide a powerful tool for the purification of MIF by solid phase affinity chromatography. Furthermore, it may provide a means of separating biochemically similar lymphocyte mediators. Work is being done to define further the nature of the binding between the gangliosides and MIF components.

Persistence of axial orientation cues in regenerating intima of cultured aortic explants

Robert W. Jackman

Department of Anatomy, School of Medicine, University of Minnesota, Minneapolis, Minnesota 55455, USA

The endothelial cells of arteries have a preferential orientation parallel to the axis of blood flow¹. This axial orientation is maintained even at the interface between two branching or anastomosing vessels1, and is re-established by newly regenerated endothelial cells in regions of intimal wounds2. The cause of the orientation, however, remains unclear. Two possibilities have been proposed, shear stress from blood flow³ and 'contact guidance' by extracellular matrix', but experiments to distinguish between them have been limited by the inaccessibility of the intima to systematic manipulation in vivo. and by the failure of organ-cultured vessels to demonstrate intimal regeneration comparable with that observed in vivo 5.6. We have recently developed a technique for the culture of whole rat aorta explants which provides easy access to the intimal surface in vitro7. Additionally, our technique provides the first organ culture system in which the regeneration of endothelium in response to wounds performed in vitro has many of the characteristics of such regeneration in vivo. By studying the migration of regenerating endothelial cells into intimal wounds produced in vitro, we have obtained new evidence in favour of the extracellular matrix as the short-term determinant of endothelial cell orientation. Moreover, although this apparent effect of the matrix can be modified temporarily by suitable wounding procedures, axial orientation cues persist even in the absence of blood flow.

Small pieces of rat aorta, pinned with glass needles to a Sylgard-coated culture dish and incubated in Medium 199 (supplemented with 30% heat-inactivated calf serum), maintain an intact endothelium, as determined by scanning and transmission electron microscopy, for as long as 10 days in culture (R.W.J., S. K. Anderson and J. D. Sheridan, in preparation). The endothelial cells respond to in vitro intimal wounds by migration and mitosis near the wound edge. A striking result is that the orientation of the regenerating cells depends on the type of wound produced.

With mechanical denudation it is theoretically possible to make four different wounds defined by the orientation of the wound edge and the direction of the mechanical stress used to make the wound. The edge of the wound can be oriented either circumferentially, as occurs in most experimental in vivo wounding procedures, or axially. The wound can be created by applying mechanical stress in the same direction as the edge or perpendicular to the edge. Thus, the following wounds are defined: (1) circumferential wounds made axially (the most common in vivo type³; see Fig. 1a); (2) circumferential wounds made circumferentially (not previously described; see Fig. 1b); (3) axial wounds made axially (related to the 'narrow scratch' wound recently reported⁸; see Fig. 1c); and (4) axial wounds made circumferentially (not previously described; see Fig. 1d). We have made all four types of wound in our aorta cultures and have monitored the endothelial regeneration for several days thereafter.

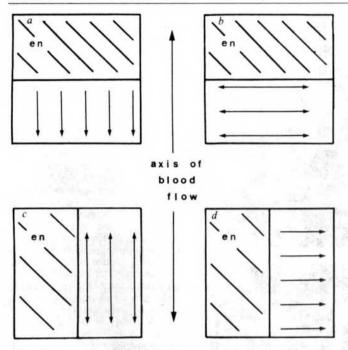

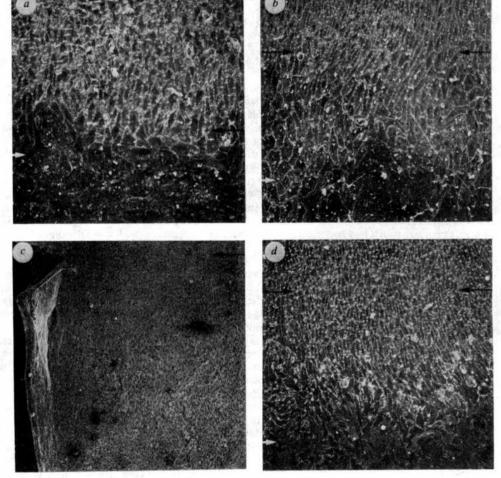

Fig. 1 Diagram of wounds made on cultured explants: a, circumferential wound edge made by wounding axially; b, circumferential wound edge made by wounding circumferentially; c, axial wound edge made by wounding axially; d, axial wound edge made by wounding circumferentially. Wounds are made with a rubber policeman at the 4th day in vitro. Unmarked arrows indicate the movement of the rubber policeman during wounding. Hatched area (en) indicates the endothelium remaining after wounding.

Figure 2a-c shows the results of regeneration from a circumferential wound made axially. After only 24 h of recovery (Fig. 2a) the endothelial cells have become elongated in an axial direction and have begun to migrate on to the denuded surface. These processes are even more apparent at 48 h after wounding (Fig. 2b). By 3 or 4 days, depending on the amount of surface removed originally, the endothelial cells completely resurface the explant (Fig. 2c). Figure 2d shows a circumferential wound made circumferentially. The preparation was fixed 48 h after wounding. It is apparent that orientation of the endothelial cells on the resurfaced area is almost exclusively axial. However, at the migrating front there is a greater degree of endothelial flattening and a more random endothelial orientation than when the wound is made axially.

When axial wounds are made, the axial and circumferential methods of wounding produce quite different results. If the axial wound is made axially there is little if any reorientation by 24 h after wounding (Fig. 3a). Any migration that has taken place has done so with a considerable axial component. By 72 h (Fig. 3b) the cells at the wound edge have maintained an axial or polygonal orientation and there has been only limited circumferential migration into the wound. Once again, any migration past the wound edge appears to have a strong axial orientation, suggesting that it is axial spill-over from the irregular wound edge. The resurfacing by the migrating cells has been inefficient and gaps remain exposing bare internal elastic lamina (IEL) in the re-established area. The failure of the endothelial cells to migrate into the wound does not result from some generalized damage of the IEL because, as shown (Fig. 3b), there is extensive axial growth from an accessory artery around which the surface was denuded during the wounding procedure. Although axial regeneration from this artery has been dramatic, as

Fig. 2 Scanning electron micrographs of explant surfaces wounded as in Fig. 1a, b. The explants were stained with silver nitrate and fixed in 2.5% glutaraldehyde in phosphate-buffered saline (PBS) for at least 4 h. This was followed by a post-fixation in 2% aqueous OsO4 for 1 h. Fixed material was then rinsed several times in PBS, dehydrated in ethanol and critical point dried in CO2 from amyl acetate. Preparations were sputtercoated with gold and viewed with an Hitachi S-450 scanning electron microscope. Black arrows indicate the approximate edge of the wound, estimated by the location of notches cut in the explant (see c). Rubber policeman wounds were begun along a line between these notches. Open arrows mark the position of the migrating wound front at the time of fixation (approximate, for irregular fronts). a, Circumferential wound edge made by wounding axially, explant fixed 24 h after wounding (×133). b, Wound edge as in a, explant fixed 48 h after wounding (×90). c, Wound edge as in a, explant fixed 72 h after wounding. Actual notch is visible in the upper left ($\times 34$), d. Circumferential wound edge made wounding circumferentially, explant fixed 48 h after wounding (×90). In all cases, the vertical axis of the figures parallels the original blood flow axis for the vessels. The circumferential wound

edge made by circumferential wounding was produced on explants from two separate rats. All the rest have been done on explants from at least three separate rats.

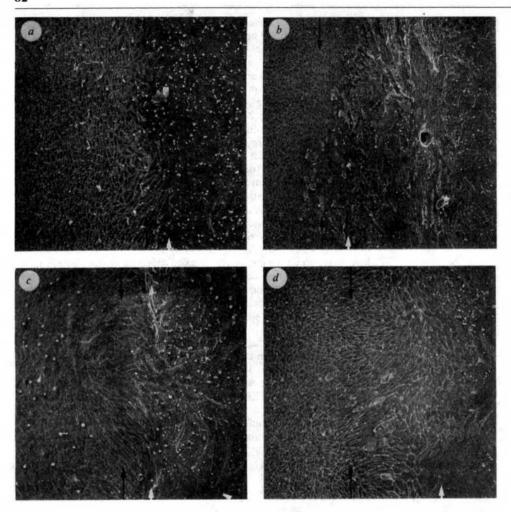

Fig. 3 Scanning electron micrographs of explant surfaces wounded as in Fig. 1c, d. The explants were preared for scanning electron microscopy in the same way as for Fig. 2, and the black arrows once again indicate the placement of the original wound edge, while the open arrows give an estimate of the extent of the endothelial migration before fixation. a, Axial wound edge made by wounding axially, explant fixed 24 h after wounding (×98). b, Wound edge as in a, explant fixed 72 h after wounding (×52). c, Axial wound edge made by wounding circumferentially, explant fixed 24 h after wounding (×82). d, Wound edge as in c, explant fixed 48 h after wounding (×55). Again, in all cases, the vertical axis of the figures parallels the original blood flow axis for the vessels.

typically seen in *in vivo* wounds, circumferential migration from the same artery has not occurred.

For an axial wound made circumferentially, endothelial cells initially elongate and migrate circumferentially (Fig. 3c). By 48 h (Fig. 3d), however, two types of orientation are visible. Endothelial cells in the area of the original wound edge are oriented circumferentially, but at the edge of the regenerating endothelial sheet the cells are oriented axially. Between 48 and 72 h no further circumferential migration takes place, and consequently, part of the original wound area remains denuded. In contrast to the results for circumferential wound edges, we have observed that the extent of circumferential orientation in these wounds is influenced by the intensity of the wound. Light wounds produce much less circumferential orientation than do heavy ones.

It seems likely that the information affecting the orientation and migration of the endothelial cells on our explants must come from either the cells next to the migrating cells or some structure or cells below the endothelium. The former theory is supported by the results from circumferential wound edges, which demonstrate only orientation parallel to the orientation of the adjacent endothelium. In contrast, on explants with axial wound edges made circumferentially, the endothelial cells are clearly able to orient, and then reorient, in each case perpendicular to the orientation of the cells which would be presumed to be the source of orientation information. We feel, therefore, that the observations are more consistent with the source being beneath the endothelial cells, and present the following working hypothesis for the involvement of subendothelial information in the orientation and migration of regenerating endothelial cells on aortic explants.

When part of the endothelium is removed, cells along the wound edge elongate before migrating perpendicular to that edge. For circumferential wound edges made axially, axial information is left intact, the elongation is pronounced and migration proceeds in a similar manner to that described for *in vivo* wound recovery². This seems to be a result of a combination of the tendency of migratory cells to invade a newly bared area (demonstrated for monolayer cultures without underlying matrix⁹) and contact guidance from axial cues⁴. In the case of circumferential wound edges made circumferentially, cells migrate in a near-normal manner but the more random orientation of cells at the migrating front suggests the partial loss of axial cues.

In the cases of wound edges which parallel the axial information, our observations support the idea that axial information not only directs endothelial migration, but may actually restrict it. For axial wound edges made axially, we believe that it is the persistent axial information which is sufficient to inhibit the elongation and migration perpendicular to the wound edge. In contrast, for axial wound edges made circumferentially, we propose that partial disruption of the axial information allows elongation and migration in a manner which seems to be due to a summation of factors similar to that for a circumferential wound made circumferentially, that is, compromised matrix information, and an heightened effect of the intrinsic tendency for cells to migrate into a bare area. Between 24 and 48 h in culture, the migrating cells of the circumferentially made axial wound edge reorient, once again aligning with the original axis of blood flow. This may indicate a regeneration of subendothelial information, or simply a change in the ability of the migrating endothelial cells to read the remaining axial information.

Other investigators have already demonstrated changes of endothelial orientation *in vivo* which must in some way involve blood flow forces^{10,11}. Our use of cultured explants has made it possible to eliminate blood flow from the factors responsible for the changes described here. However, two results from the present study seem to be important with regard to the relation-

ship between blood flow and subendothelial cues in the ultimate regulation of the orientation of endothelial regeneration in vivo. The first of these is the relative velocity of the reorientation with respect to these two variables. Changes induced by blood flow manipulation seem to require at least 3 days in vivo 10.11 and 48 h for monolayers of endothelial cells¹². Reorientation in our experiments occurs in as few as 24 h and two such reorientations can take place in 48 h. Second, our observation of the inability of the cells to maintain a migration in the circumferential direction, here in the absence of blood flow, supports data from in vivo experiments showing that endothelial cells migrate effectively against blood flow but not circumferentially3. These two points strongly suggest that there are some aspects of endothelial regeneration which are not produced by the shear forces of blood flow; that is, the structure of subendothelial information may be modified by blood flow (see ref. 4), but it is the underlying matrix which carries the imperative of orientation for migrating endothelial cells.

I acknowledge the guidance and support of Dr Judd Sheridan, valuable discussions with Dr Dale Pederson, and thank Drs David Hamilton and Michael Atkinson for advice on the developing manuscript. I thank Susan Anderson for technical training in scanning electron microscopy. This work was supported by HL 21166 to Dr J. D. Sheridan. During initial development of the techniques, R.W.J. was an NIH trainee (GM 07094).

Are there purinergic receptors on parotid acinar cells?

D. V. Gallacher*

Department of Physiology, University of Dundee, Dundee DD1 4HN, UK

ATP and other purine nucleotides and nucleosides have potent regulatory (neurotransmitter-like) actions which have been attributed to interaction with a specific plasma membrane receptor¹. To date the receptor mechanisms underlying purinergic activation have been poorly characterized. One problem has been the variability of the evoked effects in different tissues. Burnstock^{2,3} proposed that much of the variability could be explained if the effects were mediated by two separate receptors, termed P₁ and P₂, with different specificities for agonists and antagonists. Receptor mechanisms have been extensively investigated in the parotid gland⁴. I now report that in that gland, ATP evokes a marked increase in membrane conductance, radioactive Rb efflux and amylase secretion. The effects of ATP are similar to those evoked by acetylcholine (ACh) and α -adrenergic agonists but are still present when cholinergic and adrenergic blocking agents are used. The latency and reversal potential of the ATP-evoked effects are comparable with those of the autonomic agonists. The ATP receptor on parotid acinar cells is of the P₂ type^{2,3}, since the order of potency of the nucleotide series was ATP>ADP»AMP, adenosine had no effect, and the response could be blocked by quinidine but not by theophylline.

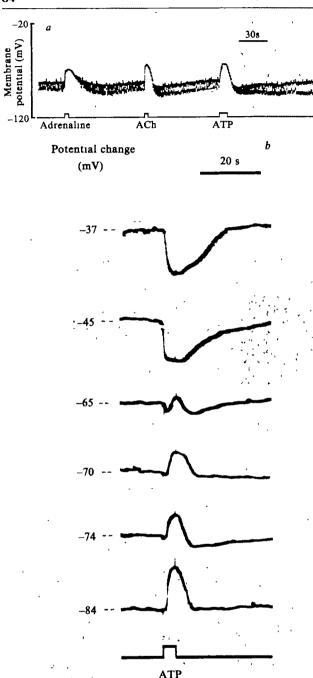

Experiments were carried out on 249 isolated parotid glands from 152 adult male mice. All glands were superfused with oxygenated physiological saline solutions at 37 °C. The acinar cell response to the various agonists was investigated using three experimental techniques: (1) single glass microelectrodes were used to record transmembrane potential and input resistance from surface acinar cells⁵; (2) the rate of Rb efflux was monitored by measuring the efflux of 86Rb from segments of prelabelled glands^{6,7}; and (3) amylase secretion was measured continuously by an on-line fluorometric method⁸. The agonists ATP, ADP, AMP, adenosine, ACh and adrenaline (Sigma) were applied by inclusion in the superfusion media, which had a final pH of 7.4. ATP, ACh and adrenaline were also applied ionophoretically from an extracellular micropipette.

The mean resting potential of the acinar cells was $-62.2 \pm$ 0.62 mV (±s.e.m., n = 74) and the mean input resistance $4.6 \pm$ $0.39 \text{ M}\Omega$ (n = 19), in close agreement with previously published values 10,11. Electrophysiological responses to ionophoretically applied ATP were observed in 69 cells from 18 glands. When the effects on the membrane of ATP and the autonomic agonists ACh and adrenaline were compared in 47 of these cells, they were all found to evoke a marked decrease in input resistance associated with an initial depolarization. This initial potential change was followed by a delayed hyperpolarization during which the input resistance returned to prestimulus levels (Fig. 1a). Such biphasic membrane responses have been previously reported in this tissue following cholinergic α -adrenergic and nervous stimulation^{9,10}

In the remaining experiments the effects of ATP were investigated in the presence of combined autonomic blockade by atropine (10⁻⁵ M), phentolamine (10⁻⁵ M) and propranolol $(5 \times 10^{-6} \,\mathrm{M})$. The autonomic blockers had no effect on the resting membrane potential and input resistance, which were $-66.3 \pm 0.67 \text{ mV}$ (n = 94) and $5.06 \pm 0.31 \text{ M}\Omega$ (n = 43) respectively. It was necessary to demonstrate the persistence of the ATP effects in the presence of autonomic blockade because the peptide hormone substance P has been shown to evoke indirect effects in this tissue by release of endogenous neurotransmitter (ACh). 11 The initial potential change of the ATP response shows the same dependence on transmembrane potential gradient as has been reported for the cholinergic and α -adrenergic responses in this tissue. Figure 1b shows the ATP effects evoked in a single cell at different levels of membrane potential. In Fig. 1c the amplitude of the ATP effects is plotted as a function of the membrane potential. The reversal potential of the ATP effect was measured in this manner on five separate occasions, having a mean of $-59.6 \pm 4.1 \,\text{mV}$ (s.d.). This reversal potential is not significantly different from the values of -58.3 ± 9.0 and -61.9 ± 8.4 mV (±s.d.) previously reported for ACh and adrenaline in mouse parotid gland 10. The latency of the effects of ionophoretically applied ATP, in the presence and absence of the autonomic blockers, was $471 \pm 33 \text{ ms}$ ($\pm \text{s.e.m.}$, n = 9) and 489 ± 58 ms (\pm s.e.m., n = 15) respectively, which is comparable with values reported previously for ACh and adrenaline in this tissue 10. The identical latency in the presence and absence of the autonomic blockers excludes the possibility of any early indirect effects11,12

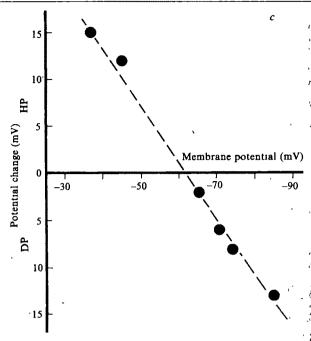

Superfusion of ATP in 55 cells from 37 glands in the presence of the combined autonomic blockers evoked a marked decrease in input resistance associated with a monophasic hyperpolarization similar to that reported following superfusion of cholinergic and α -adrenergic agonists¹³. Figure 2 shows the dose-response curve for the ATP-evoked hyperpolarizations at effective ATP concentrations of 10^{-5} – 10^{-3} M. The true dose– response curve is thought to lie to the left of the experimental one because (1) all investigations of the effects of exogenously applied ATP are complicated by hydrolysis or tissue uptake of the nucleotide²; (2) it has been reported that the α -adrenergic blocker phentolamine, at the concentration used routinely in this study to eliminate the possibility of indirect effects, will interact with the purinergic receptor¹⁴; and (3) ATP-evoked secretion in mast cells produces a similar dose-response

^{*}Present address: The Physiological Laboratory, University of Liverpool, PO Box 147, Liverpool L69 3BX, Uk.

curve^{15,16}, although in this case the true ATP agonist is the free form, the tetrabasic acid (ATP⁴⁻), which constitutes only a small fraction of the total ATP in solution ([ATP]). The [ATP⁴⁻] in the solutions used to obtain the curve in Fig. 2 (Ca 2.5 mM; Mg 1.37 mM) can be estimated as 2×10^{-7} – 2×10^{-5} M respectively¹⁵.

In parotid gland, as in other tissues, 86 Rb has been used as an indicator of potassium movement $^{6.7}$, and it is known that cholinergic and α -adrenergic agonists evoke a marked efflux of K (Rb) from acinar cells. Figure 3a demonstrates that when ATP is included in the superfusion media, even in the presence of the autonomic blockers, it mimics the effects of the autonomic agonists in its ability to evoke Rb efflux from the parotid tissue. Burnstock $^{2.3}$ describes two types of receptor—the P_1 and P_2 purinergic receptors—which mediate the effects of exogenous and endogenous nucleotides and which are identified by their different specificities for the nucleotide/nucleoside series and their susceptibility to blockade by different agonists. The nucleotide series in evoking Rb efflux from this tissue is ATP > ADP > AMP (Fig. 3a). Adenosine had no effect even at 10^{-2} M (12 glands, 3 experiments), and failed to evoke any electro-

ATP-evoked changes in membrane potential and conductance Recording of membrane potential and input resistance from acinar cell of mouse parotid gland. The potential changes superimposed on the record of resting membrane potential are due to repetitive injection of hyperpolarizing current pulses through the recording electrode (2 nA, 100 ms) The amplitude of these electrotonic potentials corresponds to the input resistance of the acinus Responses are seen to the ionophoretic application of the agonists adrenaline, ACh and ATP The initial potential change is due to an increase in passive membrane permeability primarily to K and Na. The resulting efflux of K+ and influx of Na+ stimulate an electrogenic Na/K pump, which gives rise to the delayed hyperpolarization seen when the input resistance has returned to prestimulus levels (for review, see ref. 20). The ATP micropipette contained 0 5-1 0 M ATP in distilled water. Ejection current was 300 nA applied for 8 s Responses were recorded with hyperpolarizing ejection charges of ≥50 nC. Depolarizing ejection charges were meffective as was ionophorers of a control solution of distilled water titrated to pH 3.0. Adrenaline and ACh ionophores were achieved by depolarizing ejection currents of 300 and 200 nA respectively for 4 and 3 s (ref. 9). Note the similar nature of the membrane response to the three agonists. b, Traces showing the nature of the ATP-evoked potential change at different levels of membrane potential in the same cell. The membrane potential was varied by application of direct current through the recording electrode. The superfusion media contained all three autonomic blockers throughout, atropine 10^{-5} M, phentolamine 10^{-5} M and propanolol 5×10^{-6} M. The dependence of the ATP-evoked effects on transmembrane potential is demonstrated by the reversal of the response from a depolarization (DP) at the higher levels of membrane potential to a hyperpolarization (HP) at the lower levels of membrane potential. c, The amplitude of the response (data from b) plotted as a function of the membrane potential. The reversal potential, the intersect with the abscissa, is about -62 mV Five such direct measurements of reversal potential were made with a mean of $-59.6 \pm 8.4 \text{ mV}$ ($\pm s.d.$).

physiological effects in any of nine cells from four glands when included in the superfusion media at 10^{-2} M. Histamine $(10^{-4}$ M) (8 glands, 2 experiments) also failed to evoke any increase in Rb efflux, eliminating the possibility that the ATP effects were secondary to release of endogenous histamine.

effects were secondary to release of endogenous histamine. Figure 3b shows that when 10^{-3} M quinidine was included in the superfusion media, ATP failed to evoke any significant increase in Rb efflux (36 glands, 9 experiments); subsequent application of ACh $(10^{-6} \, \text{M})$, still in the presence of quinidine, evokes the characteristic increase in Rb efflux (20 glands, 5 experiments). In the presence of the ophylline $(10^{-3} \text{ M}; \text{ Fig. } 3b)$ the ATP effect persists, unaffected (16 glands, 4 experiments). The same specificity was seen in electrophysiological experiments. ATP failed to evoke any effect in three cells (two glands) in the presence of 10^{-3} M quinidine. However, the purinergic effects were readily evoked in the presence of theophylline (10⁻³ M), by both superfusion (six cells, three glands) and ionophoresis (two cells, one gland) of the agonist. Quinidine blockade, especially at the concentration used, is not specific and more prolonged exposure to quinidine (35 min) abolished the effects of α -adrenergic stimulation in this tissue, as in others¹⁷.

ı,

The persistence of the ACh effect at this time (Fig. 3b) and later would indicate that the non-specific interaction occurs at the receptor level and is not due to a generalized blockade of the effector mechanism.

In addition to the stimulus-permeability effects, cholinergic and α -adrenergic receptor activation are associated with amylase secretion, which is characterized by its dependence on extracellular calcium¹⁸. β -adrenergic stimulation, which is not associated with any of the conductance changes described above¹⁰, is a potent stimulator of enzyme secretion, but by a mechanism independent of extracellular calcium and attributed to interaction with the adenulate cyclase-cyclic AMP system¹⁹. ATP evokes a marked increase in amylase secretion (28 glands, 7 experiments) which exhibits the same dependence on extracellular calcium (20 glands, 5 experiments) as the other stimulus-permeability-coupled receptors (Fig. 4). Adenosine $(10^{-2} \,\mathrm{M})$ had no effect on amylase secretion (8 glands, 2 experiments). The effects of the antagonists on amylase secretion could not be tested as quinidine itself interacted with the fluorometric assay.

Whereas a peptide (substance P) receptor was previously reported in rat acinar cells, but appeared absent from mouse acinar cells, in this study ATP effects were readily observed in the mouse parotid gland but could not be evoked in the rat. Superfusion of ATP (10⁻³ M) failed to evoke electrophysiological effects (6 cells, 2 glands), Rb efflux (4 glands, 2 experiments) or amylase secretion (4 glands, 2 experiments).

This study of mouse parotid gland reveals for the first time that ATP can mimic the effects of cholinergic or α -adrenergic stimulation in terms of increased membrane conductance, 86Rb efflux and calcium-dependent enzyme secretion. The persistence of the ATP-evoked effects in the presence of a combination of autonomic blockers and their short latency (equivalent to autonomic activation) suggest that they are mediated by interaction of the nucleotide with a specific surface membrane receptor. The order of potency of the nucleotide series (ATP> ADP » AMP) and the suceptibility to blockade by quinidine but not theophylline indicate that a purinergic receptor of the P₂ type is involved^{2,3}. This type of purinoreceptor predominates in the gastrointestinal system². The identical nature of the membrane responses and the common reversal potential shared by the purinergic, cholinergic and α -adrenergic agonists suggest that all three effects, although mediated by separate receptors, are the consequence of the activation of the same effector

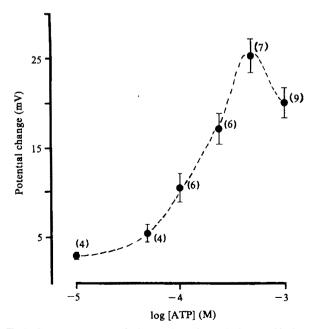

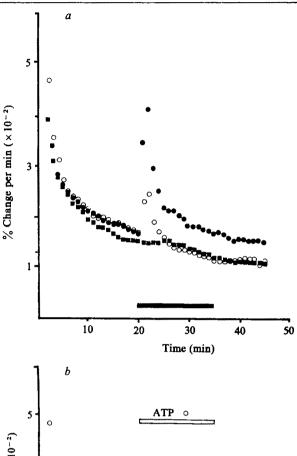

Fig. 2 Dose-response curve for hyperpolarization evoked in parotid acinar cells by superfusion with ATP $(10^{-3}-10^{-3} \text{ M})$ All experiments were carried out in the presence of the combined autonomic blockers. Figures in parentheses are the number of individual determinations. Plot is of means $\pm s.e.$

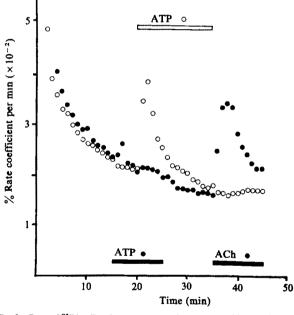

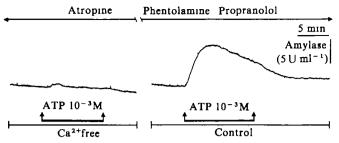

Fig. 3 Rate of ²⁶Rb efflux from segments of mouse parotid gland. In each experiment, segments of four glands were loaded with radioactive Rb for 30 mm in 1 ml of physiological salt solution containing 3-5 μCi ⁸⁶Rb. After loading the segments were transferred to a flow chamber (volume 1 ml; flow rate 2 ml min-1). The effluent was collected at 1 min intervals and subsequently analysed in a scintillation counter for ⁵⁶Rb content. The radioactivity remaining in the tissue at the end of the experiment was determined and the concentrations in the minute samples converted to rate coefficient⁶ by computer. a, Effects of purine nucleotides on the rate coefficient of ²⁶Rb efflux (given as % change per min). The agonists were applied by inclusion in the superfusion media at 20-35 min, as indicated by the bar in the figure. The autonomic blockers were present throughout the experiments. Each point is the mean of a series of experiments \bullet , ATP (10^{-3} M), n=5; O, ADP (10^{-3} M), n=3; \blacksquare , AMP (10^{-2} M), n=3. (s.e. during application of the agonists was 5-15%) The order of potency of the nucleotide series was ATP>ADP > AMP. Neither adenosine (10-2 histamine (10-4 M) had any effect. b, Effect of ATP (10-3 M) on 56 Rb efflux in the presence of quinidine (\bullet ; 10^{-3} M; n=5) and theophylline (O; 10^{-3} M; n=4). Quantitine blocks the effect of ATP applied at 15-25 min. ACh (10^{-6} M) applied in the same experiments at 35 min still evokes the characteristic increase in 86 Rb efflux. When applied at 20-35 min in the presence of theophylline, ATP evokes the characteristic increase m ⁸⁶Rb efflux. The affinities demonstrated for the agonists (ATP>ADP>AMP) and antagonists indicate that the effects are mediated by a P₂ purinergic receptor^{2,5}.

Effects of ATP on amylase release from segments of mouse parotid gland. The amylase content of the effluent from the tissue chamber (volume 1 ml; flow rate 1 ml min⁻¹) was continually assayed by an automated on-line fluorometric method⁸. The figure which is two sections of a continuous trace, shows the effects of ATP in the presence and absence of extracellular calcium from the superfusing solution. The calcium-free solution contained 10⁻⁴ M EGTA. The autonomic blockers were present throughout the experiment The ATP-evoked increase in amylase secretion is seen to depend on extracellular calcium.

mechanism. These stimulus-permeability-coupled receptors give rise to an increase in membrane permeability primarily to K and Na by a mechanism which probably utilizes Ca as a common intracellular messenger²⁰.

Neural mechanisms for serial order in a stereotyped behaviour sequence

Heinrich Reichert & Jeffrey J. Wine

Department of Psychology, Stanford University, Stanford, California 94305, USA

A single, transient sensory stimulus can evoke a complex behavioural response in which several behavioural units occur in a serially ordered manner. For stereotyped behavioural sequences, two alternative neural mechanisms have been proposed to account for the serial ordering of behavioural units: chain reflexes1, which depend on peripheral feedback, and central pattern generators2, which attribute the sequence to interactions among central neural elements. Although long thought to be mutually exclusive, both alternatives were recently shown to contribute to simple crayfish escape responses³⁻⁵. We now demonstrate that the integration of these simple, serially ordered escape responses into the compound escape sequence of the crayfish is mediated by a third mechanism for serial order, namely the parallel activation by the same sensory stimulus of two separate behavioural units with different intrinsic reaction times.

Crayfish can escape from predators by swimming backward using a series of rapid abdominal flexions and extensions (tailflips). When escape is initiated at short latency by a sudden tactile stimulus to the abdomen, an initial stereotyped tailflip is mediated by a pair of giant axons, while all subsequent tailflips (swimming proper) are produced by a non-giant central pattern . The giant axons have been termed 'command neurones'6 because, when stimulated directly, they produce an entire, coordinated tailflip. However, we recently showed that only the flexion phase of the first tailflip is produced by central action of the giants; abdominal re-extension is a chain reflex that is triggered by sensory feedback from the flexion⁵.

Proper behavioural integration requires that the non-giant central pattern generator for swimming be turned on at the right time following the first giant-mediated tailflip. How is this achieved? We considered three possibilities. First, the giant axons might trigger the central pattern generator (CPG) via a delayed, central pathway. Second, the CPG, like the re-extension reflex, might be triggered by feedback from the first tailflip. Third, the tactile, initiating stimulus might trigger both the giant axon system and the CPG in parallel. Evidence for the third alternative was obtained by stimulating directly and selectively the giant axons of unrestrained crayfish via implanted electrodes^{4,5} and comparing the resulting escape responses with those initiated by natural stimuli.

Twenty crayfish, Procambarus clarkii (of both sexes; 3-7 cm long), were kept individually in well-aerated, 40-1 aquariums. Each animal was made to respond only once per 10 min. Approximately half of the responses were produced by lightly tapping the abdomen; the other half were produced by a direct shock to the giant axons. Responses were monitored visually and via chronically implanted recording electrodes.

The result was an almost complete dichotomy in the incidence of multiple tailflips produced by natural and electrical stimuli. Following taps, ~82% of the escape responses consisted of an initial, giant-mediated tailflip followed by one or more nongiant (CPG-mediated) tailflips. But when the giant axons were stimulated directly, only a single tailflip ensued; CPG-mediated swimming was almost completely absent, occurring in <1% of all trials (Table 1). These results mean that activity in the giant axons is insufficient to trigger the CPG either via a central pathway or via feedback. Instead, excitation arising from the tactile stimulus is necessary for CPG activation.

Is the tactile stimulus sufficient to trigger the CPG, or must it be coupled with sub-threshold excitation produced by the giant axons? In the preceding experiment, only 4% of the responses were mediated by the CPG alone, which may mean that the tactile stimulus is rarely sufficient to activate the CPG, or that the stimuli used were typically supra-theshold for both the giant axons and the CPG.

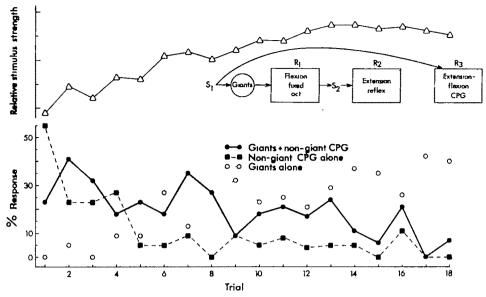

We attempted to activate the systems separately by reducing the stimulus strength so that it was just at escape threshold (50% responding), and by testing at 1-min intervals so that thresholds rose during a testing session (presumably because of habituation). Four animals were tested in this way. The results (Fig. 1) show that the tactile stimulus is frequently sufficient to trigger the CPG. Indeed, in rested animals the CPG threshold is lower than the giant axon's threshold. In the first trial, 71% of the escape responses were mediated exclusively by the CPG and 100% included the CPG (Fig. 1). (Repetitive stimulation caused the threshold for the CPG to rise relative to the LG threshold,

Table 1 Different response modes produced by central and peripheral stimulation

	Type of response Giants				
Type of stimulus	Giants	+	Non-giants		
	alone	non-giant	alone		
Shock to giant axons $(n = 445)$	99.3%	0.7%	4.0%		
Touch to abdomen $(n = 453)$	13.9%	82.1%			

Fig. 1 The block diagram illustrates the relationships between the units of behaviour that make up the crayfish escape response. The initiating stimulus activates R1 and R3 in parallel, but R3 occurs only after a delay. R2 is a chain reflex that depends on sensory feedback from R₁. The graph shows differences in initial thresholds and habituation rates of giant-mediated responses $(R_1 + R_2)$ and non-giant(CPG)mediated responses (R3). In the experiment shown, each of four animals was tested at 1-min intervals on five successive days. Thus each trial represents the average obtained from ~20 stimuli, given as per cent The responsiveness. stimulus strength (top) was increased over trials in order to maintain a total escape response rate close to 50%. Total response rates varied between 77% (trial 1) and 45% (trial 12). By

16

keeping the stimulus close to threshold we were able to demonstrate the separate response pathways Stimulus strength is indicated in relative units (peak initial amplitude of the output of a mechano-electrical transducer which was coupled to the mechanical stimulator). The three main results are: (1) the systems can be evoked independently; (2) the CPG threshold is initially the lowest; and (3) the CPG habituates more rapidly.

thus solo activity of the CPG quickly waned, with solo activity of the giant system eventually predominating.)

Given that the same stimulus can activate both behaviours in parallel, how is the serial order of the compound behaviour achieved? Previous results can now be re-interpreted to show that an intrinsic difference in response latency is an important mechanism for the sequential ordering of the behavioural units. The giant axon pathway has obviously evolved to produce responses of very short latency: the pathway is short, its neurones are large, and all known synapses except those of receptors and motoneurones appear to be electrical^{7,8}, resulting in a modal response latency of <7 ms. In contrast, the minimum latency for activation of the non-giant CPG is ~50 ms and the modal latency is >150 ms (see ref. 4). (The neural basis for the long latency of the CPG has not yet been investigated.) The latency values reported by Wine and Krasne⁴ have been confirmed in our experiments, which are based on a much larger sample size. For 180 giant-mediated tailflips, the mean latency was 6.3 ± 0.2 ms. For 63 exclusively non-giant responses, the mean latency was 240 ± 21 ms. The mean duration of the giantmediated tailflip (flexion and re-extension), occurring in isolation, was 190 ± 21 ms. Thus, it is clear that the typical latency to the beginning of CPG-mediated tailflips is long enough to allow the first two behavioural units to occur in the interim.

These results extend our understanding of how serial order is achieved in stereotyped behaviour. A previous hypothesis¹ to explain how a transient sensory stimulus could lead to ordered behavioural responses proposed that sequencing occurred because each reflex caused feedback appropriate to trigger the next reflex. Convincing examples of chain reflexes are rare^{5,9} and so far have been restricted to episodic behaviours. A second hypothesis is that order is imposed by a central pattern generator, envisaged as one or more neural oscillators. This hypothesis has been confirmed for every rhythmic behaviour whose production has been analysed carefully². Both these mechanisms are used in simple crayfish escape responses. In addition, a third mechanism—parallel activation by the same sensory stimulus of two separate neural subsystems with different reaction times—is responsible for the integration of a chain reflex and a central pattern generator into a seemingly unitary complex behavioural act.

What is the adaptive significance of the parallel processing strategy? We know that the giant axon system ignores the laterality of the stimulus and produces a bilaterally symmetrical response, whereas non-giant responses are laterally asymmetric and can steer the animal away from threat^{4,10}. Therefore, the parallel strategy may be required because the stimulus contains information that is used by the second system but not by the first.

It seems likely that reaction-time mechanisms for serial order occur widely. For example, the timing of two distinct components of the hours-long, hormonally-induced eclosion behaviour of a moth appears to rely on a reaction-time mechanism¹¹. Thus this general type of mechanism seems capable of ordering behavioural units into complex sequences of action on time scales which vary from milliseconds to hours.

FMRFamide neuropeptides simultaneously increase and decrease K⁺ currents in an identified neurone

G. A. Cottrell

Department of Physiology and Pharmacology, University of St Andrews, Fife KY16 9TS, UK

Phe-Met-Arg-Phe-NH₂, or FMRFamide, discovered in ganglia of the clam Macrocallista nimbosa1, has potent cardio-stimulatory activity in some molluscan species, but is cardio-inhibitory in others, and produces contractions of certain non-cardiac muscles². A peptide with similar properties is present in the ganglia of the snail Helix3, and is thought to differ from the Macrocallista peptide in having one or more additional amino acids combined with the terminal free amino nitrogen. An

homologous opiate peptide, Tyr-Gly-Gly-Phe-Met-Arg-Phe (or YGGFMRF, using single letter abbreviations4), was identified in adrenal medullary granules and the striatum⁵. YGGFMRFamide has chromatographic properties more similar, though not identical, to the Helix peptide than FMRFamide itself (D. A. Price, M. J. Greenberg and G.A.C., unpublished). FMRFamide has potent and complex effects on Helix neurones. One neurone in each cerebral ganglion, the C1 or giant serotonin neurone (GSN), is hyperpolarized by FMRFamide at the resting membrane level, but depolarized at less negative potentials⁶. I show here that YGGFMRFamide has similar effects to FMRFamide and examine further the ionic mechanisms underlying the two responses of the GSN. The results indicate that the hyperpolarizing, outward current response results from an increase in conductance to K+ whereas the depolarizing response, which was recorded as a reduction in net outward current, is due to the suppression of a Ca2+ activated K⁺ current.

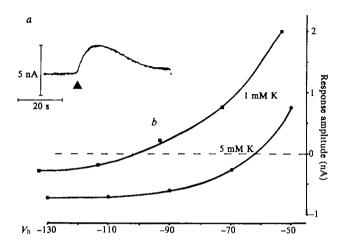

In most experiments the neurone was voltage-clamped using a Dagan 8100 single electrode system with K-acetate or KCl electrodes of $\sim 1~M\Omega$ (see ref. 7). However, responses were also recorded with a two-electrode system which incorporated either the amplifier of a Tektronics 502A oscilloscope or an RS-7611 C-Moss amplifier, in the feedback circuit. Physiological solution (NaCl 80 mM, KCl 5 mM, CaCl₂ 7 mM, MgCl₂ 5 mM, Tris buffer 5 mM, final pH 7.8) was allowed to flow continuously over the isolated cerebral ganglia preparation pinned to the base of a 0.7-ml chamber. The peptides were applied locally to the GSN either by iontophoresis (4 mM in distilled water) or by pressure ejection from a pipette (50–100 μ M concentrations of each peptide).

Each peptide hyperpolarized the GSN at the resting potential. The size of the hyperpolarizing response was increased when the external K⁺ concentration was reduced, but remained unchanged when the external Cl⁻ concentration was reduced. Under voltage-clamp, the reversal potential of the peptide-induced outward current was increased by -35 to -38 mV when the external K⁺ was changed from 5 to 1 mM (see, for example, Fig. 1b). This shift in reversal potential is close to the theoretical value of -41 mV and indicates that K⁺ is primarily, if not exclusively, involved in the hyperpolarizing response to each peptide, although the reversal potential of the response seems to be more positive for this neurone than that recorded for K⁺

Fig. 1b). This shift in reversal potential is close to the theoretical value of -41 mV and indicates that K⁺ is primarily, if not exclusively, involved in the hyperpolarizing response to each peptide, although the reversal potential of the response seems to be more positive for this neurone than that recorded for K+ responses in some other molluscan neurones (see, for example, ref. 8). The outward current response was depressed with tetraethylammonium bromide (TEA) at 30 mM, but was not completely blocked even with 100 mM TEA. It was also reduced by cooling to 4 °C. The other action of the peptides was observed at potentials less negative than the resting level. This apparent inward current response increased in size as the membrane was depolarized. Frequently a combination of both outward and 'inward' current responses was observed (Fig. 2c, d). TEA at 30 mM greatly reduced the response due to the increase in K⁺ conductance^{9,10} and revealed an enlarged, or in some cases a previously undetected, response which was inward in sign (Fig. 2a). The size of the apparent inward current response was not reduced when the external NaCl was replaced with sucrose or glucosamine hydrochloride, suggesting that neither Na⁺ nor Cl⁻ is directly involved in the response. An involvement of Ca²⁺ did, however, seem likely, as CoCl₂ at \geq 1.5 mM reversibly abolished this response (see Fig. 2b and ref. 11). On the other hand, when BaCl₂ was substituted for most of the CaCl₂ (6 mM BaCl₂ 1 mM CaCl₂), the response was also abolished. This suggested that the response was not simply due to an influx of Ca2+, but that it could result from a suppression of a K⁺ current, as Ba²⁺ can carry the Ca²⁺ current in snail neurones¹² but blocks K⁺ currents¹³. A role of K⁺ was also suggested by the results of 2 out of more than 60 experiments made with FMRFamide, in which only the inward current response was recorded. In these two experiments, the size of the response at a holding potential of -30 mV was greatly increased

on reducing the external K⁺ concentration from 5 to 1 mM.

There is some variability in the sensitivity of the delayed K⁺ and the Ca²⁺ activated K⁺ currents to different concentrations of TEA in molluscan neurones. In some neurones, both currents are equally affected whereas in others the Ca²⁺-activated K⁺ current seems to be less susceptible^{9,10}, which could explain the preferential reduction in the outward current response with

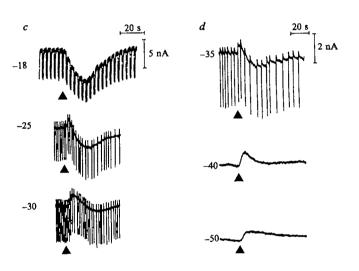

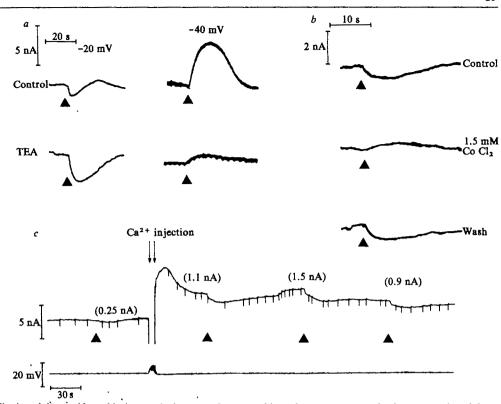

Fig. 1 a, An example of the outward current response recorded when FMRFamide was locally applied to the GSN at a holding potential of -50 mV. b, Influence of holding potential and extracellular K⁺ concentration on the size and sign of this response observed in another experiment. The reversal potential in normal medium (5 mM K) was ~-62 mV. When the extracellular K⁺ concentration was reduced to 1 mM, the reversal potential increased to ~-100 mV The nonlinear relationship between response and membrane potential is similar to that previously shown for a carbachol-evoked K+ response in Aplysia by Ginsborg and Kado⁸. c, FMRFamide responses recorded at depolarized holding potentials. At -30 mV, the outward current response was shortened to give a small response, inward in sign. At -25 mV, the 'inward current' response was greatly increased and the outward current response was reduced. At -18 mV, the response seems to consist of an 'inward current' response alone. During this recording, hyperpolarizing command voltage steps were repeatedly applied across the membrane and the resulting changes in current recorded During the action of the peptide, there appears to be a reduction in current passage These recordings should be compared with the recording in a which was obtained from the same neurone (The downward deflection on the current records at -25 and -30 mV holding potentials are unclamped spikes originating in the axon, at some distance from the site of recording.) d, Similar responses of another neurone to locally applied YGGFMRFamide. At -50 mV, there seems to be only an outward current response At -35 mV, the response was predominantly inward in sign. The outward current response was shortened by the onset of the inward current reponse in the recording made at the holding potential of $-40\,\text{mV}$. Note that in the traces shown in c and d, and also in Fig. 2, responses are recorded on top of steady outward currents. Such background currents varied to some extent from cell to cell, but with a resting potential of -50 mV they were of the order of 1.5 nA at -40 mV, 5 nA at -30 mV and 20 nA at -20 mV

Fig. 2 a, Influence of 30 mM TEA on the responses of the GSN to FMRFamide applied at holding potentials of -20 and -40 mV. At -20 mV, the control response was a composite of currents which were inward outward in sign, whereas at -40 mV the response seems to be purely outward. Exposure to TEA for 8 min, reduced the outward response at -40 mV and unmasked a response which was inward in sign at -20 mV. b, Influence of 1.5 mM CoCl₂ solution on the response. At the holding potential of -20 mV, the response was inward in sign. Exposure to the CoCl₂ solution reduced the background outward current observed at -20 mV by about 10 nA. It also abolished the inward current response and unmasked a small outward current response The effect of the CoCl2 was reversed by washing, c. Effect of locally applied YGGFMRFamide on the increased K⁺ current evoked by current evoked by intracellular injection of Ca2+. Upper trace is membrane current and the lower trace membrane voltage. The neurone was voltage-clamped at -45 mV and the peptide applied locally to the neurone. Before injecting Ca²⁺, there were only small inward current responses to the peptide. (The outward current response had been depressed with 30 mM TEA.) Injection of Ca²⁺ (40 nA for ~6s) resulted in an increase in the background outward current, that

[**4**.

is, the Ca2+-dependent K+ current. Application of the peptide at this time resulted in a greatly increased inward current response, that is, a suppression of the increased outward K+ current. The amplitude of each peptide response is indicated above the upper trace

30 mM TEA on the GSN (Fig. 2a). Of the two compounds, the YGGFMRFamide was the more potent in inducing the response which was inward in sign but less potent with respect to the outward current response.

These data suggested that the apparent inward current response could result from a suppression of a Ca2+-activated K+ current. Support for this view was obtained by testing the effect of the peptides on the increased K+ current evoked by intracellular injection of Ca²⁺ in the presence or absence of TEA. In these experiments, Ca²⁺ were injected iontophoretically using a WPI iontophoretic programmer. An electrode containing 0.5 M CaCl₂ was inserted in the neurone and a positive current of 40 nA passed for 5-15 s with respect to another micropipette placed in the medium. The cell was voltage-clamped during the injection and the membrane potential therefore remained unchanged, or was only shifted by about 5 mV during the injection period. The Ca²⁺-evoked outward current response was reversed in sign at about -65 mV in normal medium and was reversed at more negative potentials in medium with reduced KCl, as previously observed in other neurones14, establishing that the Ca2+-evoked current was due to K+. An example of an experiment showing the effect of the heptapep-tide amide on the increased outward current evoked by Ca²⁺ injection is seen in Fig. 2c, in which the neurone was clamped at -45 mV and a small inward current recorded before injecting Ca²⁺. Following Ca²⁺ injection, there was an increase in outward K+ current and the inward current effect of the peptide was potentiated as much as six times. As the increased outward K+ current declined, the effect of the peptide was reduced. It was also observed that the peptide reduced the inward current evoked by Ca2+ injection when the neurone was voltageclamped at -90 and -100 mV.

From these data it is concluded that both FMRFamide and YGGFMRFamide increase one K⁺ current, which has properties of the delayed K⁺ current^{9,10}, but suppress another, probably the Ca²⁺-dependent K⁺ current described by Meech^{14,15}. Interestingly, the polypeptide apamin, a neurotoxin of bee venom, has been reported to block the Ca2+-dependent

K⁺ channels in hepatocytes and intestinal smooth muscle¹⁶. Muscarinic agonists also suppress a K+ current, the M-current in frog sympathetic neurones, although this current is not Ca2+dependent¹⁷. The significance of the dual actions of FMRFamide and YGGFMRFamide is not known, but it is possible that if the two types of action occurred on different axonal processes of the GSN there could be a suppression of transmission via the routes on which increased conductance to K⁺ occur, but a potentiation of transmission on the routes which respond with a reduction in the Ca2+-dependent K+ conductance. The GSN has a large number of axonal processes, many of which run in parallel for long distances along some nerve trunks18. It is thought that FMRFamide and related peptides may act as hormones in molluscs², and immunoreactivity to FMRFamide has been detected histochemically in gastropod neurones19.

I thank Mr B. Powell for technical support, Professor B. L. Ginsborg for helpful comments and Drs D. A. Price and M. J. Greenberg for the gift of YGGFMRFamide.

Selective blockage of voltage-dependent K⁺ channels by a novel scorpion toxin

Emilio Carbone*, Enzo Wanke†, Gianfranco Prestipino*, Lourival D. Possani‡ & Alfred Maelicke§

* Istituto di Cibernetica e Biofisica del CNR, 16032 Camogli, Italy † Istituto di Fisiologia Generale-Università di Ferrara, Ferrara, Italy ‡ Universidad Nacional Autonoma de México, Instituto de Investigaciones Biomedicas, México § Max-Planck Institut für Ernährungsphysiologie, Rheinlanddamm 201, D-4600 Dortmund, FRG

Blocking agents of high selectivity are crucial in defining both physiologically and biochemically the molecular components that control membrane excitability. To obtain such probes for voltage-dependent ion channels, we have examined the venom of several American scorpions for the presence of polypeptide neurotoxins having the required properties. We report here that using voltage-clamped giant axons of the squid Loligo vulgaris we have identified in the venom of the scorpion Centruroides noxius Hoffmann a polypeptide (fraction II-11) that specifically depresses the peak permeability of K+ channels without affecting their voltage-dependent open-close kinetics. The venom also contains a polypeptide toxin (fraction II-10) that specifically depresses Na+ peak permeability with only minor effects on the activation-inactivation kinetics. Furthermore, the physiological effects of the whole venom on the squid giant axon can be assigned quantitatively to the combined action of the two polypeptides.

The venom of *C. noxius* Hoffmann was purified as described previously¹. Using gel permeation and ion-exchange chromatography, we isolated seven major fractions containing polypeptides toxic to mice (fraction II-8 to II-14). Of these only the minor fractions II-10 and II-11 (5 and 2%, respectively, of the total venom protein) exerted significant effects on the electrophysiological properties of the squid giant axon in the concentration range tested. Fractions II-10 and II-11 each contain only one polypeptide, but it is possible that the former also contains very small amounts of a contaminant. The N-terminal sequences of toxins II-10 and II-11 were shown to be respectively Lys-Glu-Gly² and Thr-IIe-IIe (L.D.P., unpublished observation).

Figure 1a-c shows the reversible effects of toxin II-11 on the K^+ current, I_K , of a tetrodotoxin (TTX)-poisoned squid giant axon voltage-clamped as described elsewhere3,4. On step depolarization, toxin II-11 (1.4 µM) applied externally reversibly depressed the K^+ permeability, g_K , without affecting its voltage dependence (Fig. 1d). Potassium permeability was depressed in a dose-dependent manner (Fig. 1e), suggesting interaction of the toxin with specific receptor site(s) associated with the K⁺ channel. This view is further supported by the binding and dissociation kinetics (Fig. 1f) at two different toxin concentrations. The rate of toxin association increased with increasing toxin concentration whereas the time constant of dissociation remained constant⁵. In contrast to the effects on K⁺ channels, toxin II-11 had no significant effect on Na+ peak permeability when tested separately on three axons internally perfused with Cs ions to block K⁺ currents. In addition, neither Na⁺ nor K⁺ permeability were affected by intracellular application of toxin II-11 (1.4 µM).

Only one other polypeptide (fraction II-10) of the *Centruroides noxius* venom exerted a sizeable effect on ion channels of the squid giant axon. Figure 2 shows that toxin II-10 interacted with receptor site(s) at the Na⁺ channel, thereby reducing peak Na⁺ conductivity in a dose-dependent manner (Fig. 2d), independent

dently of the voltage (Fig. 2c). The activation kinetics were influenced only marginally (Fig. 2a, b) and the maintained current levels were affected only at higher concentrations (data not shown). However, both fast and slow inactivations were unmodified and neither the holding potential nor the external Na⁺ concentration changed toxin binding⁶⁻¹¹. Together with its reversible action, toxin II-10 thus seems to have advantages over other scorpion toxins as a probe for Na⁺ channels.

In experiments using whole venom, the actions of the venom were fully reversible and the same as those ascribed to toxins II-10 and II-11, and as observed previously for a different scorpion venom¹², the size but not the kinetics of gating currents was modified by the venom.

Various effects on voltage-dependent ion channels have been reported for scorpion venoms and purified toxins⁶⁻¹⁵. Na⁺ channel blockage is rather complex and varies with the scorpion

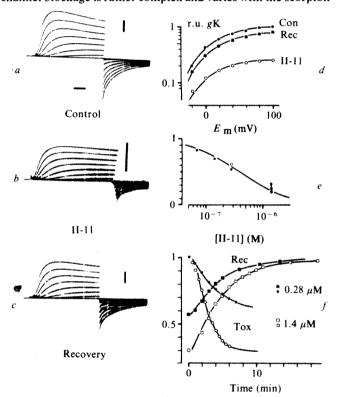

Fig. 1 Action of toxin II-11 on K^+ channels. a-c, I_K recorded at various test potentials (-20, 0, 20, 40, 60, 80 and 100 mV) before, during and after application of 1.4 µM of the toxin. Traces in b were obtained 10 min after exposure to II-11 and traces in c, 22 min after the onset of recovery. Scale bars, 1 mA and 2 ms. $E_b = -70 \text{ mV}$, $E_c = -90 \text{ mV}$ for 80 ms. Successive stimuli were separated by 3 s intervals. Positive feedback and analog compensation for leakage and capacitative currents were used. In (mM): KF (317); sucrose (307); K phosphate (45), pH 7.2. Out (mM): NaCl (435); KCl (10); CaCl₂ (10); MgCl₂ (40); Tris-HCl (20), pH 8.0; TTX (3×10⁻⁷ M). $T = 5 \pm 1$ °C. d, Instantaneous g_K in relative units (r.u.) associated with traces a, b and c as determined from the current jumps produced by step repolarizations to $E_{\rm h}$ at the end of the test pulses. The curve for control (Con) data was drawn by eye, the others were obtained by vertical shift of the same line. Rec, recovery, e, Dose-response curve of toxin II-11. Ordinate, relative $g_{\rm K}$ at $E_{\rm m}=100$ mV. The solid line is the result of a curve fit using $K_{\rm D}=390$ nM and the equation: $(1+10^{\log{\rm [TX]-\log{K_{\rm D}}}})^{-1}=g_{\rm K}({\rm TX})/g_{\rm K}({\rm C})$, where [TX] is toxin concentration, and $g_{\rm K}({\rm C})$ and $g_K(TX)$ the value of potassium conductance for the control and in the presence of toxin, respectively. KD is the equilibrium dis-

sociation constant of the reaction $TX + R \rightleftharpoons TX - R$; where R is the

concentration of receptor sites. f, Onset and offset of toxin binding measured at $E_{\rm M}=+100$ mV. Ordinate, $g_{\rm K}(t)$ normalized to the value at time zero. Solid lines are exponentials with time constants of 120 s $(1.4~\mu{\rm M})$ and 240 s $(0.28~\mu{\rm M})$ for the onset and 300 s for the offset. Tox, toxin. For clarity, complete recovery was assumed and records in c were normalized to 1 accordingly.

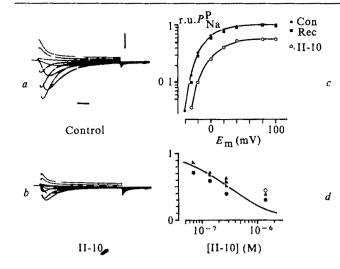

Fig. 2 Action of toxin II-10 on Na⁺ channels. a, b, Na⁺ currents recorded before and during application of 280 nM of toxin II-10. Traces in b were obtained after 14 min exposure to fraction Π -10. Recovery was complete within 35 min (not shown). Scale bars, 1 mA and 2 ms. The axon was held at $-70 \,\mathrm{mV}$ (E_b) and preconditioned to -90 mV for 80 ms (E_c) before delivering test potentials (E_t) : -40, -30, -20, 0, 20, 40, 60, 80 and 100 mV. Successive stimuli were separated by 2 s. In (mM): CsF (267); NaF (50), sucrose (307); K-phosphate (45), pH 7.2. Out (mM): same as in Fig. 1 but without TTX. T = 5 °C. c, Relative P_{Na}^{p} , peak sodium permeability, of records a and b as derived using the Goldman-Hodgkin-Katz equation 19 ; $E_{\rm Na} = 58 \, {\rm mV}$. The solid line drawn through the open circles is the same as that drawn to fit the control data but scaled in amplitude and shifted 10 mV along depolarizing voltages. d, Dose-response curve of toxin II-10. Different symbols denote different axons. Ordinate, relative P_{Na}^{P} at $E_{m} = 100 \text{ mV}$. Abscissa, molar concentration of toxin.

species^{8,15}. K⁺ channel blockage has only been described together with Na⁺ channel blockage for whole Scorpion venom^{6,13} and a toxic fraction of another venom¹⁴. Thus the important finding of the present study is that toxin II-11 acts exclusively on K⁺ channels without any significant effect on Na⁺ channel characteristics. In addition, K⁺ channel blockage is complete, independent of the applied voltage and fully reversible. These properties make toxin II-11 an excellent tool for physiological and biochemical studies of the K+ channel of excitable cells.

Compared with TTX binding to Na⁺ channels⁵ and snake toxin binding to the acetylcholine receptor^{16,17}, toxins II-11 and II-10 bind to their target sites on the squid axon with relatively low affinity ($K_D = 300 \text{ nM}$ and 390 nM, respectively) and with small association rate constants. This may be due to conformational rearrangements of the toxins required during attachment to the ion channels of the squid. More typical preys of the scorpion may have channels to which binding requires no such conformational adjustments and hence may have a larger association rate constant and lower $K_{\scriptscriptstyle \mathrm{D}}^{-18}$

Despite these minor reservations, polypeptides II-11 and II-10 seem to have advantages over previously described probes for the study of voltage-dependent Na+ and K+ channels. They have simple mechanisms of action, are fully reversible and, most important, II-11 is the first polypeptide toxin found to affect the voltage-dependent K+ channel of excitable membranes.

Triphosphoinositide increases glycoprotein lateral mobility in erythrocyte membranes

Michael P. Sheetz*, Peter Febbroriello† & Dennis E. Koppel†

Departments of Physiology* and Biochemistry†, University of Connecticut Health Center, Farmington, Connecticut 06032, USA

The finding that the turnover of the anionic phospholipid, phosphatidylinositol (PI), increases with increased synaptic activity has long stimulated interest in the possible functional roles of this phospholipid and its phosphorylated products, phosphatidylinositol 4,5-biphosphate (triphosphoinositide or TPI) and phosphatidyl-myoinositol 4-phosphate (diphosphoinositide or DPI)2. TPI metabolism is altered by a variety of cellular stimuli², but no specific function of the lipid has been identified. However, in many instances (see, for example, refs 3-6) a correlation has been observed between changes in PI metabolism and membrane structure. We have recently correlated membrane macro-viscosity with the lateral mobility of membrane glycoproteins⁷, and have shown that 2,3-diphosphoglycerate (2,3-DPG), which is similar in structure to TPI, increases glycoprotein lateral mobility. We now report that TPI also increases the lateral mobility of glycoproteins when added to erythrocyte membranes, and suggest that TPI acts similarly to other polyanions by disrupting the erythrocyte membrane skeleton.

The method of fluorescence redistribution after photobleaching (FRAP) was used to measure the lateral mobility of erythrocyte membrane glycoproteins labelled with dichlorotriazinylaminofluorescein (DTAF) as previously described8-10. We have recently shown that fluorescence photobleaching does not alter the lateral mobility of the band 3 glycoprotein in erythrocytes¹¹. The fluorescent label was primarily (65-75%) on band 3, the major anion channel of the erythrocyte, with the remainder on glycophorin and an unknown component8

Erythrocytes were lysed (1:100) in hypotonic solutions (1 part phosphate-buffered saline (PBS, 140 mM NaCl, 10 mM Na₂HPO₄, pH 7.4) and 2 parts 5 mM Na phosphate pH 7.4 with 1 mM EDTA) containing sonicated phospholipid suspensions of PI (Sigma) or ³²P-labelled DPI and TPI at different concentrations. 32P-TPI and -DPI were prepared from rat brain or from erythrocyte membranes by the method of Schacht¹², or by preparative TLC. Lipid preparations were judged to be 90% of the designated phospholipid (see Fig. 1) by two different TLC systems using commercial standards of TPI and DPI (Sigma). Sonication was performed for 10-15 min at 24 °C under N₂ in a bath sonicator to produce a clear suspension. After lysis of the cells in the presence of the lipid, membranes were incubated for 10 min at 37 °C to allow lipid incorporation and binding to occur.

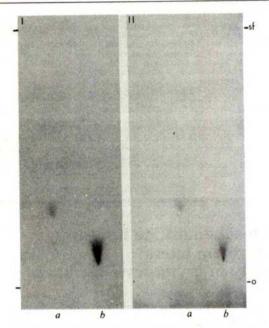

Fig. 1 TLC of 32 P-labelled DPI (a) and TPI (b) prepared by the method of Schacht¹². I is an autoradiogram and II is the material visualized by a modified Dittmer-Lester spray¹⁸. After purification, the column fractions were dried under N_2 and spotted on silica gel H (Sigma, without oxalate, 0.25 mm thick layer). Plates were developed with 1-propanol, 4 M ammonium hydroxide $(2:1)^{19}$. Sigma standards of TPI and DPI had R_F values of 0.19 and 0.33 in this system.

FRAP measurements were performed on the membranes after incubation without washing. The presence of increasing amounts of TPI in the lysis medium increased the apparent diffusion coefficient of the integral protein-bound label by more than twofold (Fig. 2). The range of diffusion coefficients for the control sample without sonicated lipid was $2.1-9.5 \times 10^{-11}$ cm² s⁻¹ whereas with 10^{-6} M TPI the range was $9.4-44 \times 10^{-11}$ cm² s⁻¹. In a paired *t*-test the average values were significantly different (P > 0.001). Figure 2 clearly shows that TPI is much more effective than DPI in increasing glycoprotein lateral mobility.

The protein diffusion coefficient is unchanged when TPI is added to erythrocytes which are swollen but not lysed in a hypotonic solution (equal parts PBS and 5 mM PO₄, pH 7.4, with 1 mM EDTA) $(4 \times 10^{-11} \, \text{cm}^2 \, \text{s}^{-1})$ compared with $4 \times 10^{-11} \, \text{cm}^2 \, \text{s}^{-1}$ for control in this experiment). This suggests that

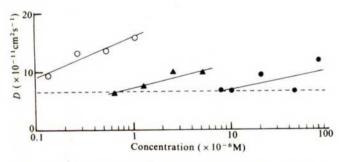

Fig. 2 The apparent lateral diffusion coefficients (D) of DTAF-labelled membranes are plotted against the concentration of TPI (\bigcirc) and DPI (\blacktriangle) , prepared by the method of Schacht¹², and PI (\blacksquare) ; Sigma). Each point is the average of four determinations. The control value (n=19) is shown by the dotted line. After pretreatment with diisopropylfluorophosphate and labelling with DTAF, cells were lysed by diluting 1:100 in sonicated suspensions of the lipids in 46 mM NaCl, 5 mM Na₂HPO₄ and 1 mM EDTA (pH7.4). Membranes were preincubated for 10 min at 37 °C before the FRAP measurement.

the active agent must reach the interior membrane surface. The observed increases in protein diffusion could not have been caused by contaminants of the lipid preparations (ammonia, ammonium acetate and neomycin). Ammonia and ammonium acetate will readily cross membranes and thus would be expected also to affect unlysed membranes. Neomycin and other amines have been shown previously to reduce the lateral mobility of membrane glycoproteins⁸. In addition, TPI prepared by preparative TLC of erythocyte membranes also caused an increase in the lateral mobility.

By analogy with previous results with 2,3-DPG, we suggest that TPI increases the lateral mobility by disrupting linkages in the erythrocyte membrane skeleton. Both TPI and 2,3-DPG have the same –5 valency, and a similar charge group structure (Fig. 3). Both are effective in increasing the lateral mobility of membrane proteins only when they have access to the cytoplasmic surface of the membrane, the surface of the extrinsic membrane matrix⁷. In many related studies, we and others have observed that 2,3-DPG and other polyanions disrupt the spectrin-actin and band 4.1 complex which comprises the erythrocyte membrane matrix¹³⁻¹⁵.

The major difference between the 2,3-DPG and TPI experiments is in the concentrations needed to produce the effects observed: 2,3-DPG will disrupt the erythrocyte membrane matrix and increase glycoprotein mobility when present in

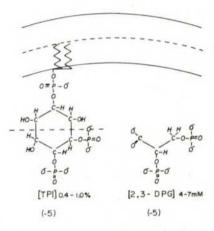

Fig. 3 The chemical structures of the lipid head group of TPI and 2,3-DPG are shown with their valency and normal in vivo concentration in erythrocytes. The concentration of TPI is expressed as a percentage of total erythrocyte lipid.

millimolar concentrations, whereas TPI is effective at the micromolar level. This difference could be explained if TPI is incorporated into the membrane bilayer, thus serving to increase its effective concentration at the membrane surface where the spectrin network is located. To assay for incorporation into cells we lysed the cells in the presence of ^{32}P -TPI. After incubation for 10 min at 37 °C, the membranes were placed on a linear sucrose gradient (1–30% sucrose in 5 mM PO₄, pH 7.4, with a 50% sucrose cushion) and centrifuged to equilibrium (30 min at 110,000g). The low ionic strength relysed the membranes, which would then float at a density of $\sim 1.15 \ \mathrm{g \, ml^{-1}}$. With both 4 and 40 μ M TPI per ml in the incubation mixture, 10% of the TPI was associated with the membrane fractions (1% cells). It is not known whether all this lipid is integrated into the membrane bilayer but it is expected that a fraction of it will be.

This information allows us to calculate the total amount of cell-associated TPI. At a concentration of 10^{-6} M, there are $\sim 10^5$ TPI molecules per swollen red cell volume, whereas in the erythrocyte membrane there are normally 10^6 TPI molecules per membrane (0.5% of total phospholipid). After incubation, approximately the equivalent of 10 cell volumes of TPI is associated with the membranes, doubling the amount of TPI in

the membrane. If some of the TPI is complexed with glycophorin^{16,17}, the added TPI may increase the amount of free TPI by more than twofold. The binding of TPI to the membrane bilayer through its hydrophobic tail will serve to increase its concentration at the membrane surface where the spectrin network is located; 1-2×10⁶ molecules of TPI corresponds to an effective concentration of 4-8 mM in a 50 Å space on the internal surface of the membrane, which in turn is the concentration range where 2,3-DPG is effective.

Thus, TPI is a potent activator of glycoprotein lateral diffusion in erythrocyte membranes, and probably acts by disrupting linkages in the erythrocyte membrane skeleton. This effect may have important consequences for such vital red cell characteristics as cell shape and deformability. In a wider context, we suggest that TPI may have a similar effect on membrane skeletal complexes in other types of cells.

Phosphorylation inhibits guanine nucleotide exchange on eukaryotic initiation factor 2

Michael J. Clemens*, Virginia M. Pain†, Sie-Ting Wong‡ & Edgar C. Henshaw‡

There is extensive evidence that protein synthesis in reticulocyte lysates is inhibited during haem deficiency because of phosphorylation of initiation factor eIF-2 by a protein kinase (the haem-controlled repressor, HCR)¹⁻⁵. Other protein kinases, which are activated by low concentrations of double-stranded RNA, have also been identified in reticulocytes 1,6 and in extracts from interferon-treated cells⁷⁻¹⁰, and these phosphorylate an identical site on eIF-2 ¹¹⁻¹². Despite the extensive documentation of such enzymes, however, the precise mechanism of inhibition has remained unclear, mainly because phosphorylation fails to affect many partial reactions of polypeptide chain initiation 13,14. We present here evidence that the exchange of GTP for GDP bound to eIF-2 is inhibited following phosphorylation of the factor. Such an effect may inactivate eIF-2 by impairing the ability to recycle between successive rounds of protein synthesis.

It has been proposed previously that the recycling of eIF-2 between successive initiation events, rather than the formation

of initiation complexes per se, is impaired by phosphorylation. Little evidence for this, other than indirect kinetic arguments¹⁵ has, however, been presented. We have been investigating the roles of the guanine nucleotides, GTP and GDP, in regulating eIF-2 activity and have previously suggested that an important step in the recycling of the factor is the need to exchange GTP for GDP^{16,17}. The former nucleotide is required for formation of pre-initiation complexes between eIF-2, initiator Met-tRNA₁, 40S ribosomal subunits and mRNA^{13,14,18} and is then hydrolysed to GDP and phosphate on or before joining of the 60S ribosomal subunit¹⁹. The eIF-2 is released from the ribosome at this stage and may remain associated with the GDP, for which it has a high affinity²⁰. GDP is a potent inhibitor of eIF-2 activity²¹ and would have to be removed very efficiently in vivo before the initiation factor could catalyse another round of protein synthesis. It is not known how this is achieved in the intact cell, but in vitro eIF-2 activity is enhanced by energy-generating systems such as phosphoenol pyruvate/pyruvate kinase¹⁷, phosphocreatine/creatine kinase²² and nucleoside diphosphate kinase²¹ (which rephosphorylate free GDP), or an enzyme which hydrolyses GDP to GMP and phosphate¹⁷. We have now developed model systems intended to reflect the process of guanine nucleotide exchange on eIF-2 in vivo and have investigated the effects on this process of phosphorylation of eIF-2 by HCR in vitro.

GDP displacement from eIF-2 was assayed by incubating eIF-2 with this nucleotide in a three stage experiment. The first stage consists of binding radiolabelled GDP to the initiation factor; binding is complete within 10-15 min at 30 °C, as measured by retention of radioactivity on cellulose nitrate filters. In the second stage the [eIF-2-GDP] complex is incubated with or without HCR and ATP. Finally, the bound GDP is displaced by adding excess unlabelled GTP (with or without initiator Met-tRNA, or GDP and the kinetics of nucleotide exchange are measured. Figure 1 shows that phosphorylation of eIF-2 after incubation with ³H-GDP has no initial effect on the amount of radioactivity already bound to the factor. The [eIF-2·GDP] complexes are also stable on further incubation (Fig. 1b). However, when unlabelled GTP or GDP is added, the labelled nucleotide is displaced with kinetics which depend on the state of phosphorylation of the factor (Fig. 1a, c). As shown in Fig. 1a, the initiation factor exchanges bound ³H-GDP for non-radioactive GTP, in the presence of MettRNA_f, over a period of 15-25 min. After treatment with HCR the [eIF-2·GDP] complexes are much more stable and do not readily exchange with GTP. In the absence of Met-tRNA, the behaviour of the [eIF-2.3H-GDP] complexes is very similar (Table 1). Phosphorylation of eIF-2 with HCR also prolongs the half life of [eIF-2.3H-GDP] complexes during exchange with a sevenfold molar excess of unlabelled GDP (Fig. 1c, Table 1).

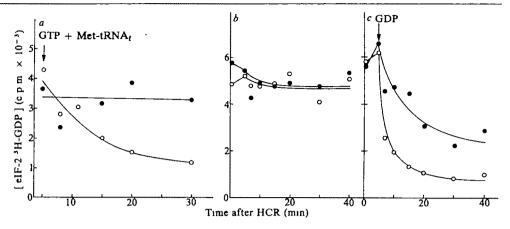

Experiments in which eIF-2 is incubated with HCR and $[\gamma^{-32}P]ATP$ and then analysed by SDS-gel electrophoresis

Table 1 Effects of HCR treatment on displacement of ³H-GDP from eIF-2

Expt	A 10 min	dditions at:	³ H-GDP bo 10 min 2 (c.p.m.×	5 min	% ³ H-GDP remaining at 25 min
1		CTD		1	
1	*****	GTP	4.24	1.62	38
	HCR	GTP	3.61	2.95	82
2		GTP	3.89	2.06	53
	HCR	GTP	3.59	3.78	105
		GTP+Met-tRNA,	4.31	2.00	46
	HCR	GTP+Met-tRNA,	3.65	3.17	87
3		GDP	2.69	0.80	30
	HCR	GDP	3,60	1.89	53
4	-	GDP	5.83	1.34	23
	HCR	GDP	5.60	4.48	80

The data summarize the results of several experiments carried out as described in Fig. 1 legend. Initiation factor eIF-2 was incubated for 10 min at 30 °C with ³H-GDP in the presence of 0.2 mM ATP; HCR (8 U ml⁻¹) was then added where indicated for a further 5 min. At this time the bound 3H-GDP was displaced from eIF-2 by addition of: expt 1, 2 μ M GTP (freshly prepared); expt 2, 50 μ M GTP (free of contaminating GDP), with or without 12.3 nM unlabelled Met-tRNA; expts 3 and 4, 2 µM unlabelled GDP.

Fig. 1 Effects of HCR on displacement of ³H-GDP from complexes with eIF-2. Initiation factor eIF-2 was prepared from a 15-1 suspension culture of ascites tumour cells suspending pelleted ribosomes in 14 ml of high salt buffer (0.25 M sucrose, 0.005 M MOPS pH 7.6, 0.5 M KCl, 0 005 M Mg-acetate, 0.001 M dithiothrestol (DTT), 0.1 mM EDTA) and re-centrifuging at 147,000g for 2 h. The supernatant (salt wash) was fractionated by ammonium sulphate pre-cipitation between 30% and 70% saturation, dissolved in 8 ml of 0.02 M MOPS, 0.35 M KCl, 0.5 mM DTT, 0.1 mM EDTA, dialysed overnight against this buffer and then subjected to chromatography on phosphocellulose (Whatman P11; 16×42mm column).

The column was washed with the above buffer, the eIF-2 was eluted with a 50-ml gradient of 0.35-0.8 M KCl in the above buffer and activity was detected by ternary complex formation (carried out in the conditions described in ref. 17). The fractions containing activity (eluting at 0.56-0.7 M KCl) were pooled, dialysed for 1 h against 0.05 M KCl in buffer, diluted with an equal volume of buffer without KCl and applied to a 3.5-ml column of DEAE-cellulose (Whatman DE-52) This column was washed with 0.09 M KCl in buffer, and eIF-2 was eluted with a 25-ml gradient of 0.09-0.4 M KCl in buffer and assayed as above. A peak containing 80% of the activity was pooled and precipitated by dialysis against 70% saturated ammonium sulphate in 0.02 M MOPS, pH 7.4. It was dissolved in 1 ml of buffer containing 0.09 M KCl and further dialysed against the latter for 1 h. The factor preparation, which was 30-50% pure, was stored in small aliquots in liquid mitrogen. The GDP displacement assay was carried out in three stages (1) ³H-GDP (6.7 µCl ml⁻¹, 0.47 µM m a; 5 µCl ml⁻¹, 0.35 µM in b and c) was incubated with eIF-2 (~12 µg of protein) in 150 or 200 µl for 10 mm at 30 °C in the presence of 0 02 M HEPES pH 7.6, 0.1 M KCl, 0.002 M Mg-acetate, 0.5 mM DTT, 0.1 mM EDTA and 0.2 mM ATP. (2) The incubation was then continued for a further 5 min in the presence of 8 U ml⁻¹ of partially purified HCR (1 unit gives 75% inhibition of protein synthesis in a reticulocyte lysate after 60 min). (3) Additions were then made of 50 µM GTP plus 12.3 pmol ml⁻¹ unlabelled Met-tRNA_t (a), nothing (b) or 2 µM unlabelled GDP (c) At the times shown, 20-µl samples were withdrawn, diluted in 1 ml of cold wash buffer (0.02 M HEPES pH 7 6, 0.1 M KCl, 0.002 M Mg acetate) and immediately filtered on 0.45 µm cellulose ester filters (Millipore). The filters were washed with 3×3 ml of wash buffer, dried and the bound radioactivity determined. a, Kinetics of dissociation of [eIF-2-³H-GDP] complexes in the presence of unlabelled GDP. O, Control eIF-2; M-

show that the presence of bound GDP, GTP or Met-tRNA_f does not affect the extent of phosphorylation of the factor in the conditions of the assays described in Fig. 1 and Table 1 legends (data not shown). Furthermore, no net phosphate is lost from eIF-2 during the longer third stage of the incubations. The data presented in Table 2 show that inhibition of guanine nucleotide exchange requires not only HCR but also ATP, and the latter must be present in a hydrolysable form. When ATP is absent or is replaced by its non-hydrolysable analogue, β , γ -methylene adenosine triphosphate, GDP displacement by GTP is unaffected by HCR treatment. These results are consistent with a need for HCR-catalysed phosphorylation of eIF-2.

A potentially significant aspect of this work is that these results have been obtained with preparations of eIF-2 which are not completely homogeneous. SDS-gel electrophoresis indicates, in addition to the major eIF-2 bands, the presence of several polypeptide components with molecular weights from 47,000 to 97,000 (data not shown). Furthermore, similar experiments using highly purified (homogeneous) eIF-2 show slow GDP exchange kinetics whether or not the factor has been phosphorylated. These results suggest that nucleotide exchange may be catalysed by another component, analogous in its action to the polypeptide elongation factor EF-Ts²³⁻²⁵. component may be present in our partially purified eIF-2 but absent from the homogeneous factor, and the interaction between this component and eIF-2 could be sensitive to the state of phosphorylation of the latter. Several laboratories have reported the existence of one or more accessory proteins²⁴ which stimulate eIF-2 activity when the initiation factor is assayed at low (physiological) levels in the presence of Mg2+, and which interact with the unmodified but not the phosphorylated form of eIF-2^{26,28-30}. Recently, a very similar factor has been characterized in the ribosome wash from Ehrlich cells and procedures have been developed for its separation from eIF-2 (L. R. V. Panniers and E.C.H., unpublished data). We are now therefore investigating the possibility that this factor acts by catalysing guanine nucleotide exchange on unmodified, but not phosphorylated, eIF-2.

During this work we have observed that not only the dissociation of GDP but also the binding of this ligand to our eIF-2 preparations is apparently inhibited by phosphorylation of the initiation factor (Fig. 2). As with the exchange reaction, the effect is totally dependent on the presence of both HCR and

ATP and is therefore unlikely to be an artefact caused by any GDP-binding or degradative activity of the HCR preparation used. There is evidence that the α subunit of eIF-2 is responsible for GTP and GDP binding¹⁸, so it is possible that incorporation of a phosphate group on this polypeptide interferes with both the entry and exit of GDP at the nucleotide binding site. Both processes could involve the putative guanine nucleotide exchange protein. Alternatively, the possible presence of unlabelled GDP already bound to the eIF-2 could prevent the association of ³H-GDP with the factor, due to inhibition of

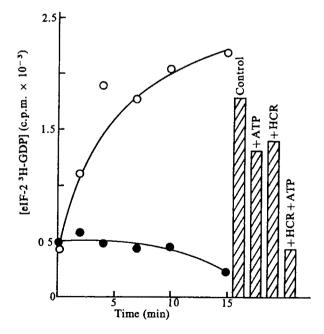

Fig. 2 Inhibition of GDP binding to eIF-2 by HCR-catalysed phosphorylation. The kinetics of binding of $^3\text{H-GDP}$ to eIF-2 were measured using the conditions described in Fig. 1 legend. Half the amount of eIF-2 was used and the initiation factor was incubated with 8 U ml $^{-1}$ HCR and 0.2 mM ATP, where indicated, for 5 min before addition of the $^3\text{H-GDP}$ at time zero. Samples (20 µl) were withdrawn at times shown for assessment of $^3\text{H-GDP}$ binding as described in Fig. 1 legend. O, Control eIF-2, \spadesuit , eIF-2 treated with HCR and ATP. The histogram shows the requirement for both HCR and ATP in the inhibition of GDP binding, measured after 7 min of incubation.

Table 2 Requirement for ATP hydrolysis for inhibition of nucleotide exchange

Additions	³ H-GDP 15 min (c.p.m	% ³ H-GDP remaining at 30 min	
ATP	7.45	1.17	16
ATP+HCR	8.25	3.42	41
Glucose +			
hexokinase	8.48	1.35	16
Glucose + hexokinase + HCR	8.65	1.08	12
AMPPcP	8.06	1.04	13
AMPPcP+HCR	9.02	1.85	21

Incubations were carried out as described in Fig. 1 legend, except that eIF-2 was incubated for 15 min at 30 °C with ³H-GDP in the presence or absence of 0.2 mM ATP or its non-hydrolysable analogue, AMPPcP, or of 10 mM glucose + 10 U ml-1 hexokinase (to remove any traces of ATP present in other components). HCR was then added where indicated for a further 5 min, at which time the bound ³H-GDP was displaced by addition of 50 µM GTP+12.3 nM unlabelled Met-tRNA_t. The data show the ³H-GDP bound to eIF-2 in 30 -µl samples removed at 15 min (immediately before HCR addition) and 30 min (10 min after GDP and Met-tRNA, had been added). Virtually identical data were obtained when ATP or glucose + hexokinase were added at 15 min rather than at zero time (not shown).

exchange after phosphorylation. The relatively slow kinetics of ³H-GDP binding to non-phosphorylated eIF-2 are consistent with such a possibility, although it is not known whether [eIF-2.GDP] complexes would remain stable through the several stages of purification involved in the preparation of the initiation factor.

In conclusion, we propose that phosphorylation of initiation factor eIF-2 inhibits the rate of initiation of protein synthesis by slowing the kinetics of exchange of GTP for GDP generated during 80S initiation complex formation. Although the results described here all concern the effects of phosphorylation catalysed by the haem-regulated protein kinase HCR, because the same site on eIF- 2α is phosphorylated by the reticulocyte double-stranded RNA-activated protein kinase, and by a similar enzyme induced in numerous eukarvotic cell types by interferons, it seems probable that protein synthesis may be similarly regulated at the level of initiation in these systems.

We thank Vivienne Tilleray and Eileen Canfield for technical assistance and Dr Tim Hunt for a gift of purified HCR. This work has been supported by USPHS grant CA-21663 to E.C.H. M.J.C. is the recipient of a Career Development Award from the Cancer Research Campaign. E.C.H. received a Wellcome Research Travel Grant for collaboration on this project.

Maternally transmitted factors modify development and malignancy of teratomas in mice

Ivan Damianov* & Davor Solter†

- * Department of Pathology and Laboratory Medicine, The Hahnemann Medical College, Philadelphia, Pennsylvania 19102,
- † The Wistar Institute of Anatomy and Biology, 36th Street at Spruce, Philadelphia, Pennsylvania 19104, USA

Maternal effects on the genome of the developing embryo have been well documented for amphibians^{1,2}. The existence of a similar maternal effect transmitted by the cytoplasm of the mammalian ovum has also been postulated but the evidence for this remains controversial and only one system, which demonstrates these maternal effects on development in the mouse, has been reported4.5. Mouse embryos (7-day-old) transplanted under the kidney capsule of adult isogeneic recipients give rise to either benign or malignant teratocarcinomas6, the yield of malignant tumours being high in some inbred strains but low in others'. In teratocarcinoma(TC)-permissive strains, such as C3H/He (C3H), or BALB/c, 50-70% of all embryo-derived tumours are malignant7, compared with only 10% in TC nonpermissive strains, such as C57BL/6. This genetic non-permissiveness is not absolute and we have shown that the outcome of embryonic transplantations depends on both the embryo and the adult recipient of the graft⁶. We now present evidence that in reciprocal F₁ hybrids, TC permissiveness is determined by maternally transmitted factors. As these matroclinous differences were evident during early stages of embryonic development when the embryo had only briefly been in contact with the uterus, we believe that the differences are due to cytoplasmic factors transmitted in the ovum rather than metabolic maternal uterine effects.

We compared the weight of tumours and the ratio of teratomas to teratocarcinomas obtained from 7-day-old mouse egg cylinders of different derivation, transplanted into isogeneic or F₁ adult recipients. The experiments were performed using embryos of two TC-permissive strains (C3H and BALB/c), one TC non-permissive strain (C57BL/6) and F₁ embryos obtained by reciprocal mating of TC-permissive and non-permissive parents. The embryos were transplanted under the kidney capsule of histocompatible female adult recipients and the tumours obtained from the embryos were collected after 2 months, weighed and histologically classified as either benign teratoma or malignant teratocarcinoma.

In the first set of experiments, we transplanted inbred embryos to either isogeneic or histocompatible F1 recipients (Table 1). The F₁ hybrids were produced by reciprocal matings to obtain recipient animals whose mother or father belonged to either a TC-permissive or non-permissive strain. The tumours obtained from transplants to isogeneic and F₁ recipient animals were histologically similar but the ratio of benign to malignant tumours varied among different experimental groups. Table 1 shows that the permissiveness of C3H and BALB/c embryos was not altered on transplantation into F₁ hybrids and the ratio of teratomas to teratocarcinomas obtained from these embryos in F₁ hybrid recipients was essentially the same as in isogeneic transplantations. In contrast, the weight of tumours obtained from both C3H (except group 4) and BALB/c embryos transplanted to F₁ hybrids was greater than that obtained in isogeneic

Table 1 Percentage of malignant tumours obtained from 7-day-old inbred embryos transplanted under the kidney capsule of isogeneic and F1 hybrid adult recipients

Group	Embryo	Recipient	No. of grafts	Mean tumour weight (mg; ±s.e.m.)	Teratoma/ teratocarcinoma	%Of malignant tumours
1	СЗН	СЗН	29	3.822 ± 460	15/14	48
2	C57BL/6	C57BL/6	30	$1,319 \pm 308$	27/3	10
3	BALB/c	BALB/c	25	$2,312 \pm 210$	9/16	64
4	СЗН	(C57BL/6×C3H)F,	37	$3,410 \pm 695$	18/20	54
5	C3H	$(C3H \times C57BL/6)F_1$	40	5.436 ± 810	20/20	50
6	C57BL/6	$(C57BL/6\times C3H)F$	49	2.714 ± 540	39/10	20
7	C57BL/6	$(C3H \times C57BL/6)F_1$	31	4.212 ± 781	15/16	48
8	BALB/c	(BALB/c×C57BL/6)F,	29	5,666 ± 682	6/23	80
9	BALB/c	(C57BL/6×BALB/c)F ₁	27	$3,780 \pm 470$	3/24	89
10	C57BL/6	$(C57BL/6 \times BALB/c)F_1$	28	$1,740 \pm 380$	24/4	14
11	C57BL/6	$(BALB/c \times C57BL/6)F_1$	34	680 ± 240	30/4	12

Inbred mice C3H/He (C3H), C57BL/6 and BALB/c, and their F1 female hybrids were obtained from Jackson Laboratories or produced in our animal colony. In F1 hybrid mice, the female parental strain is shown first. The embryos were obtained from dated pregnancies. An embryonic portion of 7-day-old embryos was isolated and transplanted under the kidney capsule of adult isogeneic or F₁ recipients. Recipient animals were killed 2 months after grafting and the tumours were weighed. Diagnosis of treatoma or teratocarcinoma was made histologically. Probability values for weight of tumours as calculated by Student's 1-test were P < 0.005 (group 1 compared with 2, 2/7, 2/3 and 3/8); P < 0.02 (10 compared with 11); P < 0.05 (8/9, 1/5, 4/5). Probability values for the ratio of teratoma to teratocarcinoma, as calculated by χ^2 test were P < 0.005 (2 compared with 7, 7/10, 7/11); P < 0.01 (6/7); P < 0.05 (10/11); P < 0.2 (2/6).

Table 2 Percentage of malignant tumours obtained from 7-day-old F1 hybrid embryos transplanted under the kidney of histocompatible F1 hybrid adult recipients

Group	Embryo (F ₁ hybrid)	Recipient (F ₁ hybrid)	No. of grafts	Mean tumour weight (mg; ±s.e.m.)	Teratoma/ teratocarcinoma	% Of malignant tumours
1	C57BL/6×C3H	C57BL/6×C3H	35	$1,469 \pm 433$	29/16	17
2	C3H×C57BL/6	C57BL/6×C3H	38	4.072 ± 850	20/18	47
3	BALB/c×C57BL/6	BALB/c×C57BL/6	29	$5,686 \pm 1,179$	14/15	52
4	C57BL/6×BALB/c	BALB/c×C57BL/6	24	$1,460 \pm 776$	22/2	8

In F, hybrid mice, the maternal strain is shown first. Probability values for weight of tumours as calculated by Student's t-test were: P < 0.005 (1 compared with 2, 3 with 4). Probability values for the ratio of teratoma to teratocarcinoma as calculated by χ^2 test were: P < 0.001 (3 compared with 4); P < 0.01 (1 compared with 2).

transplantations. The non-permissiveness of C57BL/6 embryos as evidenced in isogeneic transplantations (group 2) was abrogated in transplantation to some F₁ hybrids (group 7) but not to others (groups 10 and 11). Note that the ratio of teratomas to teratocarcinomas obtained from C57BL/6 embryos increased significantly on transplantation to (C3H×C57BL/6)F₁ hybrids whose mother was TC permissive (C3H) but did not increase in reciprocal (C57BL/6×C3H)F₁ hybrids whose mother was TC non-permissive (C57BL/6). Paradoxically, the weight of tumours obtained from C57BL/6 embryos was lower in (BALB/c×C57BL/6)F₁ hybrids than in either isogeneic or $(C57BL/6 \times BALB/c)F_1$ recipients, although the ratio of malignant to benign tumours did not change. These data indicate that the TC non-permissiveness is relative and may be modified by the host. It is also obvious that in reciprocal hybrids the malignancy of embryo-derived tumours is determined by the parental derivation of the recipients. The increased yield of malignant tumours and accelerated growth of tumours occurred only in the F₁ hybrids whose maternal strain was TC permissive (C3H).

In the second set of experiments, we compared weight of tumours and the ratio of malignant to benign teratomas obtained after transplantation of F₁ hybrid embryos to histocompatible F₁ recipients derived from matings of TC-nonpermissive C57BL/6 strain and the TC-permissive strains (C3H and BALB/c). In each combination, the materno-paternal strain derivation of recipient animals was kept constant and the derivation of embryos was reciprocal. Table 2 shows that the embryos whose maternal strain was TC non-permissive (C57BL/6) gave rise to teratocarcinomas in essentially the same ratio as the inbred C57BL/6 embryos. In contrast, the embryos whose mothers were TC permissive and the fathers TC nonpermissive $((C3H \times C57BL/6)F_1 \text{ and } (BALB/c \times C57BL/6)F_1$ embryos) gave rise to significantly more teratocarcinomas than the reciprocal hybrid embryos. The ratio of teratoma to teratocarcinoma in the two latter groups corresponded to the ratio expected from isogeneic embryo transplants of C3H and BALB/c (maternal strain) embryos.

The F₁ adult recipients and embryos produced by reciprocal mating of a TC-non-permissive and two TC-permissive strains have identical genomes notwithstanding the Y chromosome

present in ~50% of the embryos. Nevertheless, the outcome of embryonic transplantations was markedly influenced by the maternal strain of the F₁ hybrid recipient animals and even more so by the derivation of F₁ hybrid embryos. These differences indicate a matroclinous effect, but additional studies are needed to determine whether this effect is due to the maternal environment during embryonic development (the 'uterine effect') or 'cytoplasmic factor(s)' transmitted in the cytoplasm of the ovum³. The present data do not rule out either of these hypotheses. The experiments with F₁ hybrid embryos indicate that the differences between reciprocal hybrids are already evident in the early postimplantation stages of embryonic development, thus favouring the existence of cytoplasmic factors, as it is unlikely that external, maternal metabolic influences could have modified so profoundly the developing embryo, as it had only briefly been in contact with the maternal organism before transplantation.

Errata

In the letter 'T-cell mitogens cause early changes in cytoplasmic free Ca²⁺ and membrane potential in lymphocytes' by R. Y. Tsien, T. Pozzan and T. J. Rink, Nature 295, 68-71 (1982), on page 69 the concentration of the phosphodiesterase inhibitor Ro20/1724, should be 10 µM and that of dibutyryl cyclic AMP should be 0.25 mM.

In the letter 'Atmospheric angular momentum and the length of day: a common fluctuation with a period near 50 days' by R. B. Langley et al., Nature 294, 730-732 (1981), on page 732 the acknowledgement should read that R.B.L. was supported in part by a Natural Sciences and Engineering Research Council of Canada Postdoctoral Fellowship.

BOOK REVIEWS

An inspection of inspectorates

Eric Ashby

A BOOK written under the surveillance of a committee, setting out the results of a project supported by a grant from the Social Science Research Council: surely the kiss of rejection for book-reviewers! Perhaps that is why this book has received so little attention. I am glad to have the chance to redeem this neglect. For the book does not have that bland anonymity associated with such multiple parentage. The committee was a working group set up by the Royal Institute of Public Administration to assist Mr Rhodes in his research; but they left Mr Rhodes on his own to write the book and it has the imprint of a man of independent mind examining the material he has collected and coming to clear and well-argued conclusions about it. The conclusions deserve careful study and further discussion.

At the end of his book Mr Rhodes asks (though not as bluntly as this) "Are inspectors really necessary?". He explains how difficult it is to get an answer to the antecedent question: "What good do they do?", and he shows how one needs to dig into their history in order to appreciate their present usefulness. There are two kinds of inspectorates; those that have to ensure compliance with statutory requirements (enforcement inspection) and those that have to maintain or improve standards of performance (efficiency inspection). At extreme ends of the scale of inspectorates there are clear differences between these two categories: an inspector of weights and measures has to enforce the law that grams and litres used in trade are to be uniform all over the country; an inspector of schools does not have to enforce compliance with any statutory standard. But - and this is what makes the topic of inspectorates so complex and so controversial - history demonstrates that the most effective enforcement inspectorates do not depend for their efficacy on enforcement (in the literal sense). They do have the power to bring culprits to court, and on paper it may seem that their job is to act like policemen enforcing a 30-mile-an-hour speed limit. But that is not the way they work. Even factory and mines inspectors, up against bitter opposition from mill and mine owners who resented interference from the state, learnt early in their history that they got the best result from being (as the chief inspector of factories in 1878 put it) "the friend of the manufacturer as much as the friend of the employé". The first alkali inspector, charged in 1863 to enforce a 95 per cent reduction in the emission of hydroInspectorates in British Government: Law Enforcement and Standards of Efficiency. By Gerald Rhodes. Pp.281. ISBN 0-04-351056-6. (George Allen & Unwin: 1981.) £15, \$35.

chloric acid from soda works, came to the same conclusion: I work, he wrote, "at present, by advice and friendly admonition, and prosecutions will come in their proper time".

Except for flagrant and defiant offenders, the time for prosecutions never has come. This is in striking contrast to the style of administration in the United States. In the control of pollution, for example, there are at any one time hundreds of cases in the courts in the USA, compared with five or ten at most in Britain. What is the reason for this difference? One reason is that inspectorates in Britain have acquired, in over a century of practice, a discretion to make what are really quasi-political decisions, using their judgement in the way they interpret their powers under the law. There is no provision in law (for instance) for an obsolete cement works, soon to be closing down, to be allowed a greater licence to pollute than a new cement works, just being put into operation. If the alkali inspector had no more discretion than a policeman, he could not allow such licence. But - as Mr Rhodes cogently argues in his book - it is just because the alkali inspector (and the same holds for other sorts of enforcement inspectorates) has been allowed discretion that his work is, on the whole, so effective in the public interest. Inspectors who use their discretion in such ways as this are, of course, vulnerable to the criticism that they are in the pocket of the manufacturer. But on balance this tradition in British inspectorates — a discretion to compromise and bargain cooperatively with the persons being inspected — has stood the test of a century of practice.

"Are inspectors really necessary?". Of course Mr Rhodes does not answer this question, but he leaves the reader with a pretty persuasive hint that he would say: "For the present, yes". Inspectors for efficiency, in particular, help to keep standards up to the mark; and even though there is no reliable way to measure their value quantitatively, the fact that they are highly valued by the very people whom they inspect is sufficient to justify their maintenance. Everyone who is liable to be inspected (and I guess that covers most

readers of *Nature*) should find time to read this admirable book. It explains how a race of officials who in some countries are the object of denigration, have — thanks largely to the perception and tact of their Victorian predecessors — become in Britain the object of respect.

Lord Ashby was formerly Master of Clare College, Cambridge. His most recent book, written with Mary Anderson, is The Politics of Clean Air (Clarendon/Oxford University Press, 1981.)

Sense of déjà vu

H.F. Rowell

Sense Organs. Edited by M.S. Laverack and D.J. Cosens. Pp. 394. ISBN 0-216-91094-3. (Blackie: 1981.) £29.75.

THE editors of Sense Organs state their object to be to produce

a set of stimulating contributions covering what is known about how biological sensors work, their sensitivities, their ambiguities, their input to the CNS and the manner in which their signals are interpreted.

Their attempt at this enormous task amounts to less than 400 pages, and not surprisingly the result is gappy and uneven. The book consists of papers presented to the Scottish Electrophysiological Society in 1980. The contributors appear to have been drawn from those in the field who were available in Britain or Western Europe at the time, and one suspects that the immense scope aimed for by the editors was determined by the diversity of the contributors, rather than the reverse.

The patchiness of the contents is accentuated by irrational ordering. For example, an article on behavioural correlates of photoreception is placed under "Structure and Function of Sense Organs", and within each of the book's two subsections there is no grouping of articles by either modality, phylum or level of analysis. Several contributions are traditional in style: the Introduction and the Epilogue by Autrum and Loewenstein, respectively, an article on sensory coding by Bullock, one on cognition by Gregory, one on "unusual" (i.e. speculative) senses by Brown, and a general essay on modalities by one of the editors. These or their near equivalents have appeared at most

symposia in this area for the past 20 years. The remainder are of two types: general reviews of a sub-field (thus Boekh on chemoreceptors, Sandeman equilibrium systems in arthropods, or Hawkins and Korner on the acousticolateralis system, to mention three of the best), or descriptions of the author's own work. Some articles which at first appear to be reviews are actually of the second type. Of the accounts of individual work, some of the best have already, and deservedly, had extensive public exposure (for example Land on a phylogenetic dichotomy in the optics of Crustacea, and Kirschfeld on the role of photostable pigments in vision) and produce a sense of déjà vu when encountered again with the long latency of a symposium volume.

However, I found three articles stimulating. Young gives a fascinating account of his research on the bizarre eye of Daphnia, and produces biologically satisfying explanations for many of its peculiarities. Light from above appears to be recognized by its high proportion of blue, side light in alga-rich water by green colour: appropriately sensitive and spatially organized receptors coupled with suitable behaviour enable the animal to stay the right way up and near to the surface, and to find and exploit algal patches. The author also convinces one that the "tremor" characteristic of this and similar eyes is unrelated to the interommatidial angle and hence not directly subserving scanning. Stieve reviews the role of calcium in visual transduction in invertebrates, and den Otter transduction in chemoreceptors. Both accounts are lucid and interesting and include much that is unfamiliar to me. As a neuron - rather than a receptor - physiologist I found the variety of off-beat mechanisms considered striking. Thus the control of light-activated channels in photoreceptors is attributed to a Ca/Na antagonism with competition for identical binding sites, and the possibility is entertained that the receptor potential of chemoreceptors may communicate with the spike initiating zone not electrotonically but via conformational change of microtubules or even via compression waves in the plane of the cell membrane.

I have slowly come to the view that the published symposium is the least useful form of scientific publication, except possibly for the isolated graduate student in a forgotten university. In general it consists only of material more adequately treated either in research articles or in review volumes. Most of Sense Organs reinforces this opinion — the useful bibliographies and the few articles which, as the editors put it, genuinely "convey the fascination and excitement of the topic" seem barely worth the tedium of the remainder.

Astronomy: the politics and engineering

C.M. Humphries

Telescopes for the 1980s. Edited by G. Burbidge and A. Hewitt. Pp.278. ISBN 0-8243-2902-3. (Annual Reviews, Palo Alto, California: 1981.) \$27 (US), \$28 (elsewhere).

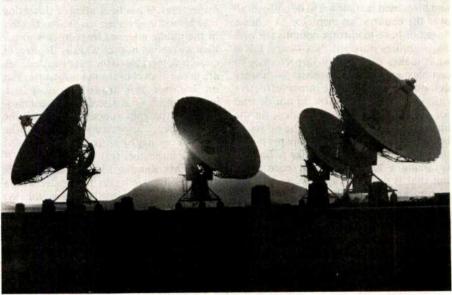

Not least among the ingredients required to bring a major national project from concept to fruition is perseverance. Budget trimming due to inflation, committee wrangles, procrastination and politics are just some of the adversities which may have to be weathered and which are all too familiar it seems, judging by the accounts of four large astronomy projects recently undertaken in the United States. Two of the projects described in *Telescopes for the 1980s* are ground-based telescopes and two are space observatories; together, they span the spectral region from radio frequencies to X-rays.

The Very Large Array was conceived in the early 1960s when it was recognized that existing radiotelescopes in the USA were incapable of extending extragalactic studies much further. Spurred by the need to create an imaging instrument with improved sensitivity and resolution, the last of the 28 movable 25m dishes (27 + 1 spare) was completed 18 years after the initial design studies began. In his account of the project, D.S. Heeschen comments that "in spite of real problems, petty irritations, miscellaneous distractions and excessive inflation, VLA construction proceeded pretty much on schedule and within budget". The result is a powerful aperture synthesis telescope with 351 separate baselines and an angular resolution of 0.1-2 arcsec depending on the wavelength band used.

The Multiple Mirror Telescope, described by authors from the participating groups at Tucson and the Smithsonian Astrophysical Observatory, is the subject of the next section. By comparison with the others, the MMT programme seems to have benefited by having a fairly loose organizational structure in its early years. Personal recollections by R.J. Weymann, former Director of Steward Observatory, give a nice insight into how that collaborative structure evolved and why it worked. On the matter of funding, the project was severely criticized at one stage for having started before financial backing was fully identified. Weymann's response to this is that "given the particular set of circumstances surrounding the MMT, to wait until funding had been located would have been tantamount to abandoning the project". A highly innovative optical and IR telescope was the result, and one which has an exciting new potential for speckle interferometry with the individual mirrors co-phased.

C.R. O'Dell's description of the Space Telescope project gives a fascinating account of the way in which new programmes evolve within NASA and of the relationship between NASA, the Office of Management and Budget (part of the executive branch of government) and the House of Representatives appropriation subcommittee. At one stage the ST was deleted entirely from the approved NASA budget for the financial year 1975 ("since the costs exceeded the choke limit of Congress"). When the project was later reinstated, the budget was less than NASA had requested, forcing a reduction in aperture to 2.4m and a re-examination of the scientific performance goals. Despite the compromises which had to be made, the 0.1 arcsec imaging capability still promises a huge observational advance.

The Einstein space observatory,

The Very Large Array — 27 mobile dishes, at maximum extension providing the equivalent of a radiotelescope 21 miles in diameter.

discussed in the final section by R. Giacconi et al., was launched in November 1978 and completed its operational lifetime 2½ years later. It, too, experienced some potentially disastrous setbacks (and had to be reduced in aperture by a factor of two) yet survived to make important X-ray observations with unprecedented sensitivity and an angular resolution (1–2 arcsec) which now matches that attainable with ground-based optical telescopes and the VLA.

Each of the sections in *Telescopes for the 1980s* contains a detailed account of the design and performance of the telescope and its instrumentation, and the sections on the VLA, MMT and Einstein observatory present examples of the scientific results obtained up to the end of 1980 (descriptions of the scientific uses of the ST are available elsewhere). The text is well supplied with diagrams and tabulated material, making a volume which is both useful and informative.

Cinderella subject

P.G. Williamson

Paleoecology, Concepts and Applications. By J.R. Dodd and R.J. Stanton. Pp.544. ISBN 0-471-04171-8. (Wiley: 1981.) £29.55, \$53.15.

THE rennaissance that has swept large areas of palaeontology over the past two decades has left palaeoecology curiously untouched. New concepts in evolutionary palaeontology, such as punctuated equilibrium theory, are currently subjects of lively controversy within general evolutionary biology: palaeontologicallybased approaches to morphological analysis - such as Seilacher's "Konstructionsmorphologie" - are major influences on neontological interpretations of functional morphology. Palaeobiogeographical investigations have provided significant insights into the development and relationships of modern faunas. Increasingly, these various fields of palaeontological investigation have made significant contributions to their neontological sister-disciplines. Up to now, palaeoecology has been a sad Cinderella, absent from this intellectual ball. The main interest of this book is that it indicates — in part at least — why this is so.

The authors' avowed intent is to illustrate the utility of palaeoecology in palaeoenvironmental reconstruction. To this end, their book consists largely of a long series of anecdotal summaries of

previously published palaeoecological analyses. Chunks of basic ecological theory are periodically interjected; these are followed by further speculations as to how insights from modern ecology might, with varying degrees of ambivalence, assist palaeoecological reconstruction in particular instances. This approach has the unfortunate effect of revealing palaeoecology as a largely derivative field, a poor-man's applied ecology performed on inadequate data.

The dreary state of the discipline is best illustrated by those cases in which intensive work over several years has permitted the comprehensive characterization of given palaeoenvironments. A case in point is Stanton and Dodd's own exhaustive - and entirely admirable - work on the Pliocene Kettleman Hills deposits of the San Francisco area. This work is used as a connecting thread to link the various palaeoecological techniques explored in successive chapters (a good idea, incidentally). Assiduous application of various techniques over several years has allowed a detailed understanding of conditions in the Pliocene marine embayment of the Kettleman Hills. The upshot of all this effort seems to be that palaeoenvironments in the Kettleman Hills during the Pliocene were, well, rather as you might expect. Salinities varied from time to time and area to area. The biota varied correspondingly and predictably from time to time and area to area. This kind of empirical analysis could be repeated a million times in the hundreds of millions of cubic kilometres of the global Phanerozoic rock record, but hardly seems a potentially fruitful research strategy for a science aspiring to an original conceptual framework.

Admittedly, these are problems of the discipline as much as of the book. But the book itself suffers from serious shortcomings. These are sins of omission rather than commission, but are problems nonetheless. There is virtually no discussion of the plethora of statistical techniques that have so usefully been applied to specific palaeoecological problems in recent years. This is particularly unfortunate as the book claims to emphasize the applications of palaeoecology. To this extent — as a teaching aid — the book compares unfavourably with such texts as Reyment's Introduction to Quantitative Palaeoecology (Elsevier, 1971). Most discussion of numerical techniques is superficial: this supposedly graduate-level text provides no usable explanation of rarefaction! Discussion of techniques for the measurement of faunal diversity surely no small matter in palaeoecological studies - merits a scant four pages, and Fisher's parameter α isn't even mentioned. You do not have to be a rabid Hennigian to wonder why an entire chapter, supposedly devoted to palaeobiogeography, lacks any reference to vicariance biogeography.

Stanton and Dodd provide a useful general survey of the palaeoecological literature. But this survey is rendered somewhat inaccessible by the fact that there is no author index. The book is overlong for what it has to say, and there is an unfortunate tendency towards Haigspeak: "Using the community... as an information transfer unit is most effective in the Neogene"! The book could be two-thirds of its length and still be an equivalent

"information transfer unit".

I suggested previously that palaeoecology has been the absent Cinderella at the modern palaeontological ball. Stanton and Dodd's book suggests that she may have some time to wait for the Good Fairy, never mind the glass slipper.

Spot the potential carcinogen

Alastair Hav

Evaluation of Short-Term Tests for Carcinogens. Progress in Mutation Research, Vol.1. Edited by Frederick J. de Serres and John Ashby. Pp.827. ISBN 0-444-00570-6. (Elsevier/North-Holland: 1981.) Dfl.295, \$125. Short-Term Tests for Chemical Carcinogens. Edited by H.F. Stich and R.H.C. San. Pp.518. ISBN 3-540-90496-4. (Springer-Verlag: 1981.) DM 142, \$64.60.

CANCER caused by contact with chemicals at the workplace and in the environment is something regulatory authorities are trying to control. The task is a daunting one. New chemicals reaching the market place each year are numbered in the thousands. Yet each chemical must be tested to assess its toxicity, and in particular its potential for causing cancer. Can this be done using tests that will satisfy the regulators, but will not bankrupt industry? And, just as important, are there assays which will give an answer in days, as opposed to the two years for the standard animal carcinogenicity study?

There would seem to be an optimistic answer to both questions. There are tests which satisfy these criteria and which can be used to predict carcinogenic activity. The first of the so called "short-term tests" for carcinogens was originally developed by Dr Bruce Ames at the University of California (the Ames test). Using bacterial strains of Salmonella, Ames showed that chemicals which caused cancer in animals would cause bacteria to mutate. This ability to cause mutation, he argued, could be exploited to test for carcinogens. Thus a chemical which was mutagenic in the Salmonella test would be considered to be a potential carcinogen.

Unfortunately it is not that simple. Neither the Ames test nor the others developed since its discovery — based on the mutation of other bacterial, fungal or mammalian cells — will identify every potential carcinogen. The short-term tests are fickle. They give better results for one class of chemical than for another. In addition, many of the tests have been evaluated with the researcher knowing both the identity of the chemical being

tested and that it is carcinogenic in animals.

This kind of information is not going to be available when new chemicals are being tested. In this case, the tests will have to predict which chemicals are likely to cause cancer. Until recently short-term tests had never been evaluated under conditions in which they would be used by regulatory authorities to identify problem chemicals.

In 1976, however, a start was made to remedy this situation. Evaluation of Short-Term Tests for Carcinogens is the result of that initiative. It is the report of a unique international programme of collaboration between scientists in many countries to look at the ability of these tests to predict carcinogenicity. The venture, started by the UK Medical Research Council and Health and Safety Executive, was broadened to include scientists from ICI's Central Toxicology Laboratory and the US National Institute of Environmental Health Sciences. The US Environmental Protection Agency and the National Cancer Research Institute in Japan also made a financial contribution to the study.

Scientists in some 60 laboratories were sent 42 chemicals, 25 carcinogens and 17 non-carcinogens. The chemicals were coded and the identities were only revealed after the investigators had submitted their final results. According to the organizers, the chemicals were selected on the basis of the information available about their carcinogenicity in animals. Examples from most of the major classes of organic chemical carcinogens were chosen, as were chemicals which are either "vital to life or are considered essential to our modern lifestyle". This latter group included three chemicals assumed to be non-carcinogens such as methionine, vitamin C and household sugar.

Because of the design of the study, the 30 or so tests under scrutiny were being evaluated as predictors of carcinogenic activity and not just as tests to look at the mutagenic properties of chemicals. Thankfully, the results of this expensive but unique exercise in collaboration show that the tests have an important role to play in any programme to screen for potential carcinogens.

In the introductory chapters to this book the editors set out the reasons for the study; the basis for selection of chemicals used; the animal carcinogenicity data on these chemicals; and a summary of the results obtained by the laboratories. In the remaining 60 or so chapters each investigating team describes their own experimental protocol and discusses the results obtained in detail.

The book contains a wealth of material which will be of immense value to anyone interested in identifying chemicals which are potential carcinogens. The results of the study show that the most effective tests are those which use bacteria such as Salmonella or Escherichia coli. However, these bacterial tests do fail to pick out some potential carcinogens which other fungal or mammalian tests will identify. But these other tests in turn fail to identify chemicals which the bacteria pick out. All tests have false negatives and false positives and the study shows that a battery of tests will be required for satisfactory results.

The unequivocal evidence about a chemical's potential for causing cancer is always regarded as being provided by tests in animals; indeed this study was based on that premise. It is somewhat ironic, therefore, that the study has shown that animal carcinogenicity data are not always as good as they might be. Azoxybenzene is said to be a non-carcinogen in animals vet many of the in vitro tests identify it as a potential carcinogen. According to one of the editors, John Ashby, this suggests that the negative carcinogenicity data on this chemical which are available may not be reliable. It is recommended that azoxybenzene should be re-tested in animals.

Imaginative titles for books on screening tests for carcinogens are obviously in short supply. Neither of the two books reviewed here has what one might call an arresting label. But the titles do at least tell the reader what he or she is going to find. The second book, Short-Term Tests for Chemical Carcinogens, contains papers from 43 experts in the field, some of whom participated in the international study. The papers describe different tests in detail and the evaluation of some of them in individual laboratories.

The value of this second volume is in the scope it gives to authors to discuss the more neglected area of viral tests for carcinogens. And some authors address the complex issues of anticarcinogens, cocarcinogens, promoters, sensitizers and DNA repair inhibitors. The role these other factors play in the mechanism of carcinogenicity is still far from clear. However, with the research effort now being devoted to this area answers will not be long in coming. These two books show that the effort so far has been worthwhile, and that the short-term test has a vital part to play in detecting potential carcinogens.

Prospect of sanity for oil prices

The weakening of oil prices in the past six months may — just may — presage the ending of the long recession. Will the oil consumers have the wit to see what they must do now?

Is the recent decrease of the international price of oil a sign that the great economic recession is about to end, or the first swallow whose appearance does not mean that summer has begun? Of necessity, there can be no quick answer. Only time can tell. But there are serious dangers in the arguments now going the rounds among economic soothsayers in the industrialized oil-consuming countries that rising prosperity is once more just around the corner. The most obvious risk is that people will now be tempted to falter in their pursuit of the strategies that have led to the steady reduction of the consumption of petroleum from the members of the Organization of Oil-Exporting Countries (OPEC), and thus to the decrease of prices in the past few months. The second risk, less obvious, is that the oil-consuming states will continue to under-estimate the need — and the opportunity — for making arrangements among themselves for buffering the cost of oil against the fluctuations decreed by OPEC and others.

That the weakening of oil prices could be a cheerful sign is beyond dispute. Just as successive increases of the international price of oil since 1973 helped to create the blend of price inflation and economic deflation that has hamstrung the oil-importing states, so a reduction of price should have the opposite effect less rapid inflation, more economic activity and people spending less on petroleum products and thus having more to spend on other things. The calculation is that a 10 per cent fall of oil prices should reduce the costs of goods and services by about one per cent and yet lead to an increase of demand in the oil-consuming states of about 0.5 per cent. The decrease in the price of oil in the past six months is more like 12.5 per cent than 10 per cent, but the economists are right to say that even the small reductions of prices and small increases of production that would result would feed on each other. In any case, the optimists argue, there may be further reductions of oil prices in the months ahead and so, with luck, a recovery of many industrialized economies.

Before throwing their hats in the air, the oil consumers should think harder than is their habit about what lies ahead. Although the decision by Saudi Arabia to reduce its oil production by 1 million barrels a day (50 million tonnes a year) will not directly affect the now weak international market for oil, it may ensure that the emergency meeting of OPEC provisionally arranged for 18 March is less incoherent than its immediate predecessors. For OPEC is far from dead, the jubilant obituaries of the past few weeks notwithstanding. But OPEC, commonly called a cartel. has yet to demonstrate that it can function at a time of falling demand for oil as a means of restricting output on a scale sufficient to influence the international price of oil. Its essential weakness is that many of its members have come to look to the whole of their oil revenues for their own economic support, with the result that they cannot with equanimity contemplate either a reduction of the price of oil or a reduction of their own exports. Apart from Saudi restraint, the only substantial restriction of exports that there has been so far has been caused by the determination of Iran and Iraq to do as much damage as they could to each other's oil installations as part of their private (and pointless) war. Yet even an agreement to a temporary reduction of exports, say for six months, could, if it were substantial, steady the falling price of oil and perhaps even make it rise again. The swallow that the industrialized oil importers have joyously been contemplating could quickly vanish.

More lasting economic forces within the oil-consuming states will also help to moderate the rosy prospect ahead. If the price of oil decreases, some plans for exploiting marginally economic reserves of oil and natural gas in the oil-consuming states will have to be postponed, moderating the rising trend of oil consumers' domestic production in the past few years. In any case, if industrial production does pick up again, so will the demand for oil. And if OPEC can find a basis for functioning as a true cartel. fixing the price and agreeing within itself not to break the rules even if exports should fall drastically as a result, its members' reduced demand for goods and services will partially offset the expected increase of economic activity among the oil consumers. So the economic recovery now possible is by no means a foregone conclusion. And to the extent that the oil consumers are by no means in charge of events, they will simply have to hope for the best in the next few weeks.

At the same time, they should recognize that whatever happens within OPEC will not bring back the circumstances of a decade ago, when the international price of oil was roughtly a tenth of what it has become. Not merely has much of the oil that used to be extracted from the Middle East at a cost of \$1 a barrel or less already been sold, but the arrangements that have been made in the oil-consuming states to increase domestic production (Britain, in the North Sea, for example) provide a floor below which the price of OPEC oil need not fall. OPEC members would more readily settle on a rational policy in the next few weeks if they were given some kind of assurance that, even in present circumstances, none of their customers is looking for a return to the prices of the 1950s. Ever since 1973, the oil consumers have set their faces against anything that might smack of joint negotiation on the international price of oil — and they have been justified by the events of the past few months. Now, though, when the boot is on the other foot, it might make sense that the oil consumers should break silence to give their suppliers an intelligent account of what the next decade holds.

More of the same will be the best recipe. Only now, a decade after the price of petroleum increased fivefold in as many months. have the benefits of conservation become apparent in the energy budgets of the oil consumers. Both in the United States and, to a lesser extent, in Western Europe, industrial users of energy have understandably led the way. They have been encouraged to invest in energy-saving equipment by the high costs of oil and of equivalent fuels. Japan, almost wholly dependent on imported fuel, has done even better - again for reasons that are entirely understandable. But what the experience of the past few years has shown is that energy conservation is necessarily a slow process, one in which the cost of energy is only one of several influences. The doubt now raised by the falling price of oil is that the continued hankering of some governments, that of the United States especially, to shield people from the true cost of energy for political reasons will take the edge off the incentive to energy conservation. (Exhortation will not do instead, for although a barrel of oil saved is exactly equivalent to a barrel of oil extracted from the ground, saving oil when it would be cheaper to burn it is an economic waste.) The trend, apparent in the past few years, is to replace oil by other sources of primary energy. The modest reduction of the price of oil should not, however, take the wind out of the sails of nuclear energy programmes, or even schemes

for turning coal into alcohol or sunlight into electricity, provided they are strictly economic.

There are also more subtle steps to take. The oil consumers should have been heartened by the demonstration provided in the past few years that even when a commodity is inherently as scarce as crude petroleum, it cannot be indefinitely insulated from market forces. If the real price is too great, people will use something else or will use less energy. And while prices can be kept artificially high for a short time, such a state of affairs cannot persist. What the oil consumers should ask themselves is whether this time of relative plenty in the supply of oil should not be used as an opportunity for making the international market in petroleum more effective. One snag is that the past decade has persuaded too many of them that their domestic supplies of oil, however small, should be reserved for domestic consumption. This is the spirit in which the United States Congress has in the past insisted that Alaskan oil should not be exported direct from Alaska, and in which the British Parliament has repeatedly asked that oil from the British sector of the North Sea should first be landed in the United Kingdom. The long-term interests of both countries would be better served, however, by making sure that this substantial quantity of oil could be used as a way of making a true market price for oil

Free broadcasting

The British government has been converted to telecommunications. The other side of the coin is freedom.

Technological developments, frequently subversive of accepted economic truths, are occasionally a challenge to social norms. The technique of in vitro fertilization as a means of producing children may be such a case. The new techniques of telecommunications are a more immediate challenge, especially where governments have been unwilling to acknowledge which way the wind has been blowing. This challenge will soon crop up in Britain, where the government announced last week that it would indeed take up the licence granted to it (and all other sovereign states) by the conference of the International Telecommunications Union in 1979, and launch a directbroadcasting satellite. By all accounts, this development is part of a recent and belated conversion of the British government to the belief that satellite communications have a brilliant future and, more surprisingly, to the view that it will be a social benefit if most British dwellings can be "cabled up" - linked to some broadband distribution system capable of handling more like forty than four distinct video signals, as at present.

The belief that the time has come when a choice of television signals may be a social benefit flies in the face of the entire history of British broadcasting. While the government's conversion (see page 105) seems to stem from a calculation that there is money to be made by manufacturing equipment that can also be sold elsewhere, what it has forgotten is that all its predecessors have fought hard for the notion of public service broadcasting, the Reithian concept that electromagnetic waves are inherently different from other kinds of communication in that they are best used for the transmission of seemly messages, educative ideally, if entertaining then, in the last resort, improving. The subliminal knowledge that the British Broadcasting Corporation is the world's outstanding practitioner of this art may have helped, as much as the soundness of its plans, to persuade the British government to give the coporation the first refusal of the licence to use two television channels on the first British direct broadcasting satellite in 1985.

That is the thin end of the wedge. The way technology has developed, television signals have become a kind of token contraband—if they exist, and people hanker after them, people will find some way of seeing the pictures that they represent. At the worst, they may have to buy a video-recorder and the cassettes to go with it. Or a domestic dish with the appropriate re-coding equipment. Either way, the new technology limits the degree to

which the authorities can control what people see or hear by means of broadcast signals. But how can this knowledge be squared with what successive British governments have been saying within living memory — that there must be central control not merely of the signals but of their content? Charters approved by parliament at present restrict what can be broadcast by both the British Broadcasting Corporation and its commercial counterparts. Both kinds of organizations, for example, are enjoined to strike a political balance in the content of what they broadcast and not to offend public taste. From time to time, they get into trouble, and questions are asked in the House of Commons. But this happens only infrequently. For the most part, all concerned are united behind the principle that broadcasting is a community service which, until the past few weeks, has even lent support to the doctrine put forward by the Annan committee three years ago that it would be wrong to sanction pay-television lest that should allow some people to see television programmes denied to others, that it should permit the broadcasting of indecencies and (under Labour governments) that it should allow commercial companies as yet unlicensed to make a profit.

That mask must now crack, although it is far from clear whether the present British government has accurately appreciated the difficulties it will face in converting a voting public from the present condition in which television signals are needlessly scarce to one in which all those who wish to send out broadcast signals, and who can pay the cost, will be allowed to do so. There will be fierce opposition from those who protest that a free-for-all will spell the end of quality in British broadcasting. (Less Shakespeare, no "Upstairs, Downtairs" or "Brideshead Revisited".) Sir Harold Wilson, once prime minister, will be only one of those who argue that providing more opportunities for would-be broadcasters will pave the way for what he called "cultural pollution" two years ago. Perhaps the British government is calculating that, with all the delay that there has been, the pent-up sense of opportunity among would-be investors in new broadcasting systems is so great that they will put up with the most restrictive fine print on whatever licences they are given.

The truth, however, is that even now, the British government is moving too slowly. And the accident that the International Telecommunications Union has allowed each sovereign state in the Old World the right to a single geosynchronous satellite is technically a red herring, an artificial spur to decision. For if a commodious cable system is economic for a country such as Britain, a single satellite will not be able to fill it with signals, which in any case could be distributed more economically in other ways. Satellites do, however, have the administrative advantage that it is possible to think of licensing those who wish to use them, while preventing those who wish to broadcast only by cable from putting their signals out. The trouble with such an arrangement is that it would be hopelessly uneconomic, and illiberal as well. It would be better that the British government should face at the outset the fact the creation of a national cable television system financed with private funds entails the abandonment of the old paternalism of the regulation of what is broadcast, however well that may have been accomplished.

For practical purposes, this is what has already happened in the United States. As on many other issues, Britain is being dragged along reluctantly, and a decade or so behind. As on previous occasions, the change when it comes will not be as traumatic as is feared. Elsewhere, however, things are even worse. In France, for example, the Mitterrand government, still flushed with its election victory, undertook to dismantle the apparatus of day-today control under which French broadcasting labours resentfully. Last July, the government's appointed committee suggested how this should be done. Now, the government seems to be having second thoughts. Governments that would not dream of censoring written communications plainly, but wrongly, think that electromagnetic signals are fair game for government licensors and inspectors. They should understand that they can no more embrace this new technology while keeping the old regulatory procedures than they could require horseless carriages to be preceded on the highways by a man with a red flag.

0028-0836/82/100102-01\$01.00

Legal shadow over laser patent

First court verdict for Gould claims

Washington

The simmering debate over who should be credited with the invention of the laser entered a new phase last week when a federal judge in San Francisco, spurred on by a New York technology investment company, upheld a patent issued to physicist Dr Gordon Gould as taking precedence over the original patent issued to Dr Charles Townes and Dr Arthur Schawlow in 1960.

Dr Townes shared the Nobel prize, with two Soviet physicists, in 1964 for his work in quantum electronics and microwave spectroscopy leading to the development of the laser or Light Amplification by Stimulated Emission of Radiation. Dr Schawlow shared the Nobel prize for his work as a chemist in the same area last year. Both are generally credited with putting forward the first conceptual design for a laser in a scientific paper published in *Physical Review* in December 1958 (112, 1940; 1958).

Dr Gould, however, who worked a few doors away from Dr Townes's laboratory at Columbia University in New York in 1957, claims that a notebook kept at the time demonstrates that he was the one to coin the word laser. He also claims that his conception, as described by his investment company backer, was that of an amplifying device, and should thus entitle him to credit for the conception of the laser as a whole.

It could not be established on Monday whether Dr Gould's claim extends to the basic process by which photons are amplified within a laser or to some other feature of the device. The substance of the claim appears to be the notion of creating a population of excited atoms, capable of stimulated emission, by exposing a gas or other material to an intense flash of light.

Dr Gould's claims for patent rights extending to an estimated 25-35 per cent of all lasers on the market, have been vigorously pursued by a New York-based company Refac Technology Development. With another company, Patlex of Pennsylvania, Refac has bought 80 per cent of any royalties generated by Dr Gould's patent for a sum claimed to be over \$2 million, and says it is now defending his claims to the laser against those of the scientific and technical establishment.

Until last week, the courts had been relatively unsympathetic. Dr Gould has failed several times to have revoked the patent granted to Townes and Schawlow in 1960, when both were working at Bell Laboratories, on the grounds that he had

been the first to conceive a complete working laser.

In 1977, however, the US Patent Office awarded Dr Gould a patent on his claim to have designed the amplifying device referred to in the patent. Since then, Refac has sought to obtain royalties from all companies producing optically-pumped lasers, and says that on the basis of a 1979 patent, also granted to Gould, it will now seek royalties on the use of such lasers.

Last week's decision, the first time that the validity of the patent has been tested in a federal court, was based on a suit filed by Refac against the Palo Alto-based company General Photonics claiming infringement of Gould's patent rights and demanding royalties on all lasers produced by the company since 1977.

Refac claims that Dr Gould should have received the technical — if not the scientific — credit for the first laser. The arguments

convinced Judge Samuel Conti and, as a result of his ruling in favour of Refac, General Photonics has agreed to pay the company 8 per cent of all its future sales.

Dr Arthur Schawlow, now professor of physics at Stanford University, has said that the US Patent Office was wrong to issue Dr Gould with the 1977 patent, and that Dr Townes "may have told Gould what he was doing" during conversations at Columbia in 1958. Dr Shawlow also says that drafts of the subsequent *Physical Review* paper were already circulating in the laboratory in August 1958, the date on which Gould wrote down some of his ideas.

Mr E.M. Lang, president of Refac, argues conversely that Gould spoke to Townes about his ideas on how to produce an amplifier that would make the laser work, and that it was Gould's ideas which were later incorporated into early laser designs for which Townes and Schawlow

UN university goes on tour

Paris, February

Global modellers, the inheritors of those who gave us *The Limits to Growth* in 1972, gathered here from 22 to 25 February to advise the Tokyo-based United Nations University on its preoccupation with the problems of agriculture, energy and development. The symposium, organized by Professor Maurice Lévy of the Marie and Pierre Curie University (otherwise Paris VI), seems not finally to have persuaded the university to take global modelling to its bosom, but the rector, the Indonesian Soedjatmako, and his four vice-rectors undertook to brood about the problem when they are back in Tokyo.

Part of the interest of the occasion was that it showed how stimulating modelling techniques of socio-economic problems have proved to be, if only as a spur to understanding how one variable is related to another. Thus a model of the rural economy of Bangladesh was widely acclaimed, but the work of the International Institute for Applied Systems Analysis, of the Organization for Economic Cooperation and Development and of Dr Sam Cole (University of Sussex) also received high marks.

Professor Donella Meadows, who has been working on a model of the rural economy of New England since her collaboration on the original Club of Rome report, argued passionately at the symposium for a kind of global network of global modellers, linked together by communications satellites and thus able to exchange information or computational codes easily. The United Nations University cautiously withheld its blessing.

One of the problems of such occasions is that the participants are in two camps —

those who would construct models that address some tangible aspect of a problem and those who hold that complexity is of the essence. Some of the most confusing (and energetic) contributions to the discussion came from those who argued that "techno-economic" models purporting to account for, say, the effects of fuel prices on food production, were certain to be inadequate, given their neglect of "socio-political" considerations.

The interest of the United Nations University in these studies stems from its wish partially to focus its interest on the encouragement of economic development on what the symposium called "the energy-agriculture nexus". Inevitably, in a gathering of systems analysts, some argued that "food" would be a better variable than "agriculture".

The United Nations University is not so much a university as the late U Thant's creation of a United Nations development agency. Its chief source of funds is a pledge of \$100 million from the government of Japan. The university has no students, while all its employees are on short-term contracts. According to Soedjatmako, negotiations are now under way for a permanent building in Tokyo, although this is unlikely to be built before the end of his term of office in 1985.

Lacking a permanent establishment, the university works chiefly by forming links with academic groups elsewhere, in industrialized and developing countries alike. It was encouraged, at the end of its four-day stand in Paris last month, to be told by the newly created minister of external affairs at the French Department of Education that French academics will be asked to collaborate with the university.

had been awarded the patent.

The scientific record is sufficiently ambiguous to allow for conflicting interpretations of the facts. Lang argues that the details of a proposed amplifier included in the Physical Review paper and the subsequent patent were shown not to work, and that Gould's ideas should therefore take precedence. Schawlow's response is that the existence of a working amplifier was implied in the paper, and that even though the specific solution suggested did not succeed, other lines of approach were suggested which proved successful. He also maintains that ideas about possible amplifiers were part of the "state of the art" at the time, and hence not eligible for patent protection on behalf of any one individual.

Refac is using last week's decision to bolster its claims on behalf of Gould. Its share price rose 12 per cent in value after the verdict had been announced. However, others are unconvinced; Dr Schawlow says that the case was poorly defended by General Photonics, which has already admitted that it does not have the money to mount an appeal.

More telling is likely to be a separate suit filed by Refac against Control Laser of Florida, a leading manufacturer of optical lasers. This suit was filed within a few days of the patent being granted in 1977, and has already attracted wide interest from other manufacturers (who once intended to join the suit in opposition to Refac, but then decided to withdraw for fear of being challenged on anti-trust grounds).

When the Control Laser case comes to trial, the company stands to lose a considerable amount of money if the verdict goes against it. Mr Robert van Roijen, the company's president, said last week that the major point of dispute was whether Refac's 1977 patent covered merely the optically-pumped amplifier described in the patent application, or whether — as Refac claimed — the patent could be taken to cover the whole apparatus.

Mr van Roijen would be willing to pay royalties on the amplifier, but denies that a laser patent is involved because "it would cost only a few thousand dollars". His arguments are expected to be backed by Dr T.H. Maiman, a director of Control Laser, who was the first to publish details of a working model of the laser (*Nature* 187, 493; 1960).

Looming on the horizon, however, is another suit which Refac has filed against a separate company for infringement of the "use" patent; in this case, General Motors has joined the proceedings on the side of the defendant.

Refac continues to characterize such disputes as a David-and-Goliath conflict. The companies maintain that Refac is using Gould's research to support a position that has been consistently rejected by the courts, and that the San Francisco verdict was, in Mr van Roijen's words, a "travesty" that is unlikely to survive the next legal round.

David Dickson

Pest research centres

Foreign labs shut

New Delh.

Accusations that the big powers conduct espionage or militarily oriented research under the guise of science collaboration in developing countries have again surfaced in the wake of the recent expulsion of an American scientist, Dr David R. Nalin, from Pakistan. The expulsion followed allegations that the United States aided Pakistan Medical Research Centre (PMRC) in Lahore which he headed was engaged in research on the use of mosquitoes in germ warfare. Six years ago another US funded mosquito control project in India was closed down by the government following similar allegations.

Dr Nalin denies the charge. In an interview he said the allegation was part of a Soviet smear campaign against the United States in retaliation against American accusations that the Soviet Union had indulged in germ warfare using mycotoxins in Kampuchea. Dr Nalin claims that his centre was infiltrated by left-wingers who organized strikes and spread rumours of a connection between PMRC and the Central Intelligence Agency. Nalin said that one member of his staff had been shown to have Soviet connections. He said

Expulsion denied

Washington

The Pakistani embassy in Washington denied last week that Dr Nalin had been expelled from the country because of the allegation over his involvement in bacteriological warfare research.

The Minister of Information at the embassy, Mr M.I. Butt, said that it had been decided not to renew Dr Nalin's two-year contract as director of the Medical Research Center in Lahore after it expired last August because of what he described as Dr Nalin's failure to stick to procedural requirements for administration and research, and tension with other members of the centre's staff which eventually led several of them to resign. However he added that Dr Nalin had been allowed to stay in Pakistan until the end of January in order to complete a report on his research.

Dr Nalin, speaking from the University of Maryland, said that the future of the research centre was now uncertain, since applications for renewed funding from the Agency for International Development and the National Institutes of Health had been disrupted by his departure. He also said that the head of the department, Dr R.H. Baker, was expected to take over the temporary running of the centre until its future had been decided.

David Dickson

that a Russian, Iona Andronov, who was found one day in the centre, turned out to be a reporter for the Soviet magazine *Literaturnya Gazeta* which "exposed" the centre in an article that was picked up by the world press.

There is some evidence that there were doubts in government circles in Pakistan over Nalin's centre even before the latest accusation of impropriety. Knowledgeable medical sources in India say that Pakistani scientists have been unhappy about PMRC for quite some time. It seems that Nalin's centre had been warned not to open a phial of Japanese encephalitis virus that had been brought for an experiment when it was well known that the disease does not occur in Pakistan.

Nalin admits that his centre had been engaged in work on Japanese encephalitis, but says that the work stopped some time ago. He denies that the unit ever handled genetically manipulated strains of Aedes aegypti mosquitoes as alleged by the Soviet press. Nalin said the centre's work was mainly on two species of Anopheles mosquitoes that carry malaria, a major problem in Pakistan. According to Nalin, PMRC had conducted pilot studies on control of the malarial mosquitoes by the release of sterile males and had developed an efficient way of sexing the mosquitoes to make the technique effective.

Nalin is associate professor of international health at the University of Maryland, which set up the medical centre in Lahore in 1961. Before becoming director of PMRC, Nalin worked on diarrhoeal diseases in Bangladesh at another United States funded unit run by Johns Hopkins University. That unit was expelled from India in 1975 following uproar in parliament about its activities in Calcutta. Among the reasons for its expulsion were its link with the US biological warfare laboratory in Fort Detrick and the US Navy and the fact that its American staff made frequent trips to India's border areas.

According to Nalin there is a similarity between the allegations of germ warfare that led to his expulsion from Pakistan and those raised in the Indian parliament in 1975. The Indian unit was said to be engaged in the release of genetically manipulated strains of Aedes aegypti, the vector of yellow fever which does not exist in India. The experiments to control a vector of a non-indigenous disease raised a furore and the parliamentary committee alleged that the US experiments were part of a programme to develop yellow fever as a germ warfare weapon. The Indian government closed down the New Delhi research unit despite protests from the World Health Organization (WHO) under whose aegis it was set up.

Nalin is not the first American scientist to have been expelled from the Indian subcontinent. Dr Carl Taylor, head of the Division of International Health at Johns Hopkins University, has been told by the Indian government not to come to India in any professional capacity — although he is still allowed into the country as a tourist. Taylor ran a nutrition project at Narangwal in the Punjab for some 15 years from 1960. This project, also funded by the United States, was closed down following allegations that it had been spying on the nearby major Indian airbase at Halwara. Taylor, who was recently passing through Delhi, denies any such charges.

After the closure of the WHO unit in New Delhi and the projects run by Johns Hopkins University, the Indian government has become more strict in the scrutiny of all projects involving foreign collaboration. A central agency that includes the defence adviser has been set up to give foreign-aided projects security clearance. For the past three years the United States has been trying to mount an earthquake project in Shillong and a sedimentology project in the Bay of Bengal. But both projects have been turned down — Shillong is in the politically troubled north-east region while India is sensitive about allowing geological studies in the Bay of Bengal with its huge oil K.S. Jayaraman

Space communications

UK jumps in

Britain is to have a fully-operational direct broadcasting satellite by 1986, the earliest date foreseen in a Home Office report on direct broadcasting by satellite published just under a year ago. The government's approval for the project last week reflects the urgency with which it now views the exploitation of space and information technologies. It hopes that an early start to the project will give British industry the chance to demonstrate its capabilities and to compete in the world telecommunications market.

The satellite's two direct broadcasting channels have been awarded to the British Broadcasting Corporation, largely because its plans for using them are most advanced. It was also announced last week that British Aerospace, GEC-Marconi and British Telecom are to form a joint venture called United Satellites to build the satellite system. The three companies are now consulting with N.M. Rothschild & Son, the merchant bank, over ways of raising approximately £150 million venture capital for the project.

The BBC will lease its two channels, while British Telecom may use another for telecommunications. The plan is to go straight into a fully-operational system involving two satellites in orbit (one a spare) and a third waiting on the ground. According to British Aerospace, the satellite will be based on the ECS, a telecommunications satellite built by the European Space Agency for which British Aerospace was the main contractor. Earlier suggestions that the satellite should be

based on L-sat, the second generation of European telecommunications satellites, were abandoned partly because L-sat will be unnecessarily sophisticated and too late.

The BBC will finance its operations mainly out of subscriptions for the programmes carried on one of the channels. One channel will carry repeats of programmes already shown on its two conventional TV channels and the other will be a pay-TV channel showing recently-released feature films and the pick of programmes from foreign television.

Viewers will be able to tune into the satellite by means of small domestic dishes. They may also be able to receive programmes relayed by cable from community dishes. Government plans for cable systems are to be announced shortly, although the Home Office refused this week to comment on a report in last week's *Economist* that the government is urgently considering plans to lay optical fibres between major cities and coaxial cable between households.

Nevertheless, last week's announcements are evidence of the British government's anxiety that Britain should catch up with other industrialized nations, especially France and Germany, which have been quicker to acknowledge the challenge of space and information technologies. Other moves to exploit some of the lessons Britain has already learnt in space technology, for example through its membership of the European Space Agency, may be expected within a year or so. Officials at the Department of Industry are working on a plan to increase efforts in maritime communications and on a national earth resources programme, part of which would be Britain's contribution to the European Space Agency's proposed Earth Resources Satellite.

Whether these proposals will involve Britain launching its own satellites and just how much public money will be available to fund them, however, remains to be seen.

Judy Redfearn

Information service

Online Britain

Pergamon-InfoLine, the online scientific and technical information service of the Pergamon/BPC Group, was launched this week by Kenneth Baker, Minister of State for Industry and Information Technology. Infoline will not only be available in the United States but in Britain will represent the first commercial carrier of scientific and technological databases. Although a fledgling from the home nest — its London-based computer - the company wants to break into the markets of Europe and North America and become a "world force in the growing online information industry". A new system, Video PatSearch, is to spearhead its marketing initiative.

For an annual subscription of about

£7,000 plus online connection charges (£35 per hour), Video PatSearch will provide an in-house patent search service. The system, which would sit compactly on a large desk, is the first of its kind to link an online terminal with new video disc technology to enable users to retrieve both drawings from the original patent specification and text. At present the system, which will operate in North America and Europe, is geared to the 750,000 US patents issued scine 1971.

Hitherto, a subject search of US patents on file at the US Patent Trademark Office has been possible only by using the US Patent Classification System. A search on the computer system may take only 10 to 15 minutes on the average. Video disc technology opens the way to online access to other databases covering subjects where graphics display is necessary.

InfoLine was first set up in 1978 by a consortium including the Department of Industry, the Chemical Society of London, the Institute of Electrical Engineers and the British Library. A long period of development produced only a limited number of databases and in 1980 the partners decided they were unwilling to invest further in the project. The Pergamon Group stepped in and saved InfoLine from liquidation. Several million pounds went into the setting up of an operation based on the advanced VAX 11/780 computer system.

InfoLine complements BLAISE, the online medical retrieval service of the British Library. The databases offered by InfoLine include CA Search, the Chemical Service Databases; Compendex, the engineering database; PIRA Abstracts, covering the paper, publishing, printing and packaging industries; Management Marketing Abstracts and GeoMechanics Abstracts. All of these databases have been available in the United Kingdom and Europe, via EURONET, for some time. They will now be offered to the US market. PatSearch, the database of US patents, on the US market for two years, will now be offered worldwide from the London computer.

At the opening both Kenneth Baker and Robert Maxwell, chairman of Pergamon-InfoLine, seemed optimistic that InfoLine would flourish where other government-backed schemes had failed. The minister referred to InfoLine as a "tiny bird that escaped the net" (of nationalization).

Jane Wynn

Belgian science policy

Harsh criticisms

Brussels

The parlous state of Belgium's science policy reflects the political and economic problems facing the country. The universities, which shoulder the bulk of state-financed research, are suffering particularly badly from budgetary cutbacks, and there are loud calls for the government

to make radical changes in research funding. At the same time, the unequal way in which government-funded research centres are concentrated in the more prosperous Flemish half of the country is the source of bitter complaints from the French-speaking Walloons.

The present escalation of the language war comes in response to the threat of major closures in the steel industry of the already economically depressed Wallonia, and has led Walloons to seek out other injustices to attribute to the present Flemish dominated coalition government.

Belgium has three national research centres, the Centre pour Energie Nucleaire at Mol in Flanders and the Institut de Radioéléments and the Institut National des Industries d'Extraction, both in Wallonia. Eighty-seven per cent of all the government subsidies in question are spent at Mol if the employment created by the nuclear research centre in related industries is taken into account. The last coalition government attempted to redress the balance, at least in terms of energy research, by favouring the coal industry. But this still left 70 per cent of government research funds being spent on nuclear energy compared with 6 per cent on extractive industries. Philippe Maystadt, Science Minister in both the present and previous governments, seems to have done little to soothe Walloon anger since increased expenditure on nuclear energy and solar energy mainly benefits Flanders.

The bad blood between Walloon and Flemish scientists is overshadowed by the crisis facing universities throughout Belgium. A law passed in 1971 lays down that universities are allocated a certain sum of money for each student and out of this the university has to pay for administration, teaching and research. Maystadt ruled out specialist centres for postgraduate research as an unjustifiably expensive way of funding research for a small country.

Research is thus left largely under the control of the university authorities, loosely supervised by a ministerial and an interministerial committee for science policy. In 1981, the universities spent BFr 25,000 million (£290 million) compared with BFr 15,000 (£170 million) million at other national or international research centres. This has led the universities into a trap with administrative and other running costs rising above the price indexation system and the allocations per student falling below the index increase. The universities have therefore started to cut back on research spending.

With the policy of budgetary restraint being followed by the present government, the problem is worsening. Professor André Jaumott, ex-chancellor of the Université Libre de Bruxelles, wants universities to separate their teaching and research functions, with no budget restrictions.

Maystadt has other plans. His ministry has asked Belgian industry and the state

New broom in Spain

Barcelona

Professor Federico Mayor Zaragoza, the new Spanish Minister of Education and Science, is assessing the draft of a law for scientific and technical research which should provide a framework for scientific research in Spain, something that has been almost untouched since General Franco's time.

Professor Mayor is well versed in the higher education and science politics of Spain, having occupied many key posts: rector of the University of Granada, acting president of CSIC (the Spanish science research council), president of the "Comisión Asesora" (the main fund for research grants) and "subsecretario" (vice-minister) of education and science. He is now professor of biochemistry at the Autonomous University of Madrid and director of the Institute of Molecular Biology which is a unit of the "Centro de Biología Molecular Severo Ochoa". He was elected MP for Granada in 1979, but later resigned to become deputy director-general of UNESCO.

According to the draft law, the government intends to specify who will formulate Spanish science policy, who will control the different levels of organization and how research will be financed. It puts research under the control of a secretary of state who will report directly to the prime minister. An advisory committee, mainly composed of scientists, will propose general plans and priorities and submit an annual budget for research to parliament.

No change will be introduced in the structure of research bodies such as CSIC but, to circumvent the fact that these bodies have only permanent staff, a new institution will be created, which will be a public company that will employ research staff and act as an auxiliary to research centres. This will also facilitate the exchange of scientists between research institutes and universities. The draft will be offered for discussion to research institutions before going to parliament. However, new elections will take place before March 1983 and it is unlikely that such a complex law would pass through parliament before then.

Pedro Puigdoménech

departments what their research requirements are for the coming five years. On the basis of this information, research contracts are being handed out mainly to medium-sized companies to undertake this sort of applied research. For 1980–82, BFr 1,000 million (£11 million) has been allocated on projects such as optic fibre technology for the Belgian PTT. Solvay, the Belgian chemical giant, should also benefit from funding for industry-orientated biotechnology.

Jasper Becker

Martial law in Poland

Fresh appeal

A former president of the Polish Academy of Sciences, Dr Janusz Groszkowski, has sharply criticized a group of more than 140 intellectuals and academics who last month sent to the Sejm (parliament) an appeal for the ending of martial law.

The letter, which was also addressed to the United Nations General Assembly and the UN Commission on Human Rights, said that the imposition of martial law was contrary to the right of every nation to selfdetermination, and the freedom to determine its own political status and to ensure its economic, social and cultural development. This principle, it said, was the basis of the renewal movement which sprang up in Poland after August 1980. The letter particularly deplored "the attempts to divide the nation, setting workers against soldiers and the militia, the blockade of the means of communication in the whole country, the brutal breaking of workers' strikes by the militia and army, the internment of many thousands of people in prisons and camps. Cultural life. education and learning, it said, are being "paralysed", and the media rendered

Dr Groszkowski did not disagree with the content of the letter, nor with the demand that the authorities should "put an end to this confrontation with their own people". He felt, however, that the fact that such a letter was sent to the Sejm - a body which during the Gierek regime had totally lost the confidence of the Polish nation and indeed of the Communist party - did not give legitimacy to it. The Sejm, in its present form, is a creation of the Gierek period, now being exposed as an era of distortions and corruption. To approach an institution where people linked to the Gierek era are still active, was, he felt, "a serious political error".

Dr Groszkowski's letter reveals how little the reforms of the past 18 months have affected those in high places. In September 1980, a letter from Dr Groszkowski prompted the academy to call for major reforms in Polish political and academic circles from the Sejm downwards, to clean up political patronage and restore honesty and fair dealing to public life. Any appeal from Dr Groszkowski carries considerable weight among Polish academics - in 1976 he resigned as president of the academy when he was unable to gain legal redress for Mrs Aleksandra Hankus of the Krakow Technical University. Mrs Hankus had suffered 11 years of official harassment and almost a year in prison for libel after protesting, in 1964, that her research results had been stolen by a person enjoying political patronage who then went on to gain a doctorate on the strength of her work. Vera Rich

Weapons in space

High frontiers

Washington

America should exploit its lead in technology over the Soviet Union to pursue an aggressive space-based military and industrial strategy that would provide a "technological end-run" around the Soviet military threat, according to a report published last week by the Heritage Foundation, a conservative Washington think-tank.

Describing a scheme for integrating various space-based technologies, from orbiting battleships capable of shooting down Soviet nuclear missiles to vast solar-power satellites, the report suggests that exploiting what it calls the "high frontier" of space could solve many of the nation's industrial and energy problems while providing effective military defence.

Both the political and the technical communities in Washington are sceptical of the proposal. Many question its technical feasibility; others claim that the projected cost of \$50,000 million over 10 years is unrealistically low.

However, the Heritage Foundation hopes that its proposals will capture the imagination of those in Congress and the Administration prepared to back an ambitious, space-based military strategy, and it suggests that in the long term it could prove much cheaper than developing nuclear weapons.

The general approach has some influential support. Last week, for example, Dr Richard DeLauer, Under-Secretary of Defense for Research and Engineering, told members of Congress that he believed the Soviet Union could be deploying laser weapons in space as early as 1983, and might have elaborate space battle-stations by the 1990s.

Such speculation was dismissed as "nonsense" by several members of the Defense Science Board, who claimed that an operational Soviet space-based laser was at least ten years away. However, Defense Secretary Casper Weinberger last Thursday quoted Dr DeLauer in support of the Administration's request for sharply increased defence expenditures to offset the Soviet lead in areas such as laser weaponry. (President Reagan is asking for \$433 million for research into laser weapons for the fiscal year 1983, compared with about \$340 million this year, and only \$165 million two years ago).

The Heritage report suggests a three-layered defence against a Soviet missile attack. The first would consist of 432 satellites orbiting the Earth, each carrying conventional heat-seeking rockets, and capable of detecting and destroying a Soviet missile soon after launch. This would be backed up by satellites with more advanced weaponry capable of intercepting re-entry vehicles in mid-course. Finally US missile silos would be protected

by non-nuclear projectiles capable of blowing up incoming warheads.

Heritage officials claim this scheme would both defend the United States against Soviet missiles with a 95 per cent chance of success, and could protect Western Europe against intermediaterange missiles. Their report encourages the development of space-based industrial processing and of the solar power satellite, enthusiastically endorsed by many leading aerospace companies but reported on sceptically last year by both the National Academy of Sciences and Congress's Office of Technology Assessment.

Assessment of the technical feasibility of the proposed programme varies widely. There is general support for some of the less radical technology that would be involved, such as the missiles used for silo protection, but greater doubt about the advanced systems needed to detect and destroy Soviet missiles.

Other uncertainties surround management, cost and political acceptability. On the first, the foundation suggests a dedicated national effort comparable with the Manhattan Project which, it claims, could have an operational system in place within five or six years. On cost, it estimates a total of \$50,000 million, of which \$35 million would be redirected from other areas of the defence and intelligence budgets, and the remainder from the National Aeronautics and Space Administration. General Daniel Graham, who was military adviser to Mr Reagan during the 1980 election campaign and is a former director of the Defense Intelligence Agency, headed the nine-member panel which put together the report. He admitted that this figure might be unrealistically low, but added that "even if we are 100 per cent under, we are offering a strategic bargain".

The whole proposal, however, raises arms control problems that may mean indefinite delay. For example, it would fuel Soviet criticism that the space shuttle is essentially a military programme. The satellites might also be accused of violating the UN Space Treaty, signed by both the United States and the Soviet Union in 1967, which prohibits the stationing of weapons of mass destruction in space.

Finally any hint of a shift in military and strategic planning away from the MAD doctrine would resurrect the heated technical debates of the late 1960s over the adequacy of defence measures, at that time over anti-ballistic missiles. Critics such as Dr Kosta Tsipis of the Massachusetts Institute of Technology and Dr Richard Garwin of IBM have been quick to point out that any space-based weapons system based on sophisticated communications is highly vulnerable to enemy attack.

General Graham said that a copy of the report had been passed to the Office of Science and Technology Policy, which is preparing a report on the future of the American space effort, and whose director, Dr Jay Keyworth, has been keen to explore ways of exploiting the capability of the space shuttle. Dr Keyworth, however, is not expected to show much sympathy for the more radical technical proposals being suggested by the Heritage Foundation. He has already resisted congressional pressure to build and operate high-energy laser battle-stations for space defence against ballistic missiles. Orbiting battleships are unlikely to gain more approval — although they may get on to the list of advanced military technologies which is expected to appear on the Agenda of the new Science Council. David Dickson

Bangladesh conference

Fertile minds

Dacca

Agricultural and rural development were dominant themes at the conference of the Bangladesh Association for the Advancement of Science held in February at Joydebpur, twenty miles north of Dacca. The conference was opened by Justice Abdus Sattar, President of Bangladesh, who urged scientists to bend their energies towards self-sufficiency in food, population control and the development and exploitation of indigenous resources.

Professor A. K. Aminul Huq, this year's president of the association, pleaded in his address for the planned development of manpower to meet the needs of the domestic agricultural industry and of those "manpower importing countries" in which people from Bangladesh find jobs. He said more use should be made of agricultural wastes as a source of energy and pleaded for more government support for science and technology, given the enormity of the problems with which these professions can assist.

More immediate assistance with agricultural development is likely to flow from an agreement now reached between the government and the Saudi Fund for Development. The fund will provide US\$80 million — part grant, part low interest loan — towards the cost of the Chittagong fertilizer factory, which should be completed in 1985.

This project will cost \$467 million, and the plant will have a daily output of 1,000 tons of ammonia fertilizer and 1,700 tons of urea fertilizer. It has been financed by the Asian Development Bank, the Overseas Economic Corporation of Japan, the Abu Dhabi Fund for Arab Economic Development, the Canadian International Development Agency and the Islamic Development Bank.

When signing the most recent loan agreement, the managing director of the Saudi Fund for Development, Mr Mohammed Abdullah Al-Sugair, said that he would be recommending that the fund should be more sympathetic to the needs of Bangladesh. The fund is supporting six projects at a total cost of 727 million Saudi rials (£116 million).

M. Kabir

CORRESPONDENC

Flower power

Sir — It is to be hoped that the outcome of Indian production of paper from water hyacinths, Eichornia crassipes (Mert.) Solms (E. speciosa Kunth.), reported by Jayaraman1, will be more successful economically than previous attempts to use the plant's fibre in this way.

His statement that "all efforts so far have been directed at eradication of the weed" overlooks some interesting developments elsewhere. It is only in slow-moving waterways that the species becomes a pest. Soon after its introduction into Hong Kong and South China, in the first decade of this century2. came cultivation, primarily as a feed for pigs. taking full advantage of the rapid multiplication of the plant. It is grown in South China today, in ponds and flooded fields, as a feed for livestock and poultry3. Burnt, it can be a useful manure, because of its high potash content.

Where it is plentiful, and not required for other purposes, straw is probably preferable as a source of paper, because of its higher yield4.

Wages of war

SIR — It would be a disservice to the scientific community if the assertions of R.G.S. Bidwell (Nature 11 February, p.452) were allowed to stand unrepudiated. This author clearly sees a direct link between the imposition of sanctions and the waging of war, and appears to welcome the opportunity of contributing to it. He refers disparagingly to the activities of pacifists in the Great Wars, not realizing that their efforts in the First World Disarmament Conference were within a hair's breadth of creating conditions which would make war an impossibility. Sanctions, on the other hand, can do nothing but increase the likelihood of war, because they only serve to nourish suspicions of malevolent intent on both sides. Never have Soviet scientists that I have spoken to expressed any desire to destroy us, as Bidwell is close to suggesting.

No scientist working for the benefit of humanity can surely wish to be associated with the notion that science is "ours", not "theirs", because we have paid for it. If the fruits of science are not made available to others, then it is of no earthly use. If the science we do in our laboratories is considered unsuitable for widespread application, it is better left undone. What we pay for is the prestige of making a discovery, the benefit to our industry of detailed technical knowledge and experience, and the chance to contribute to mutual understanding between nations, but not for the right to deny this knowledge to the rest of the scientific community.

Lack of understanding through insufficient information gives rise to some of the grossest iniquities in the world today. The eclipse by the Polish situation of the tragic events taking place in El Salvador is a direct result of restriction of flow of information. It is

important that scientists should avoid involvement in such a practice, and refrain from endorsing the dubious and hypocritical moral judgements of our cold-war strategists.

Myth or fact?

Sir - Is the creation versus evolution argument really irreconcilable?

To those who cling to every word of the Bible nothing can be said. But surely the Old Testament and other ancient texts are the repository of ancient knowledge. Perhaps the creation is a distant "folk memory" reinterpreted by succeeding generations - of events that actually took place at a time (15,000 vr BP?) beyond documented recall.

The geological evidence is that marked changes in the environment took place at the Pleistocene/Holocene boundary. Could the ancient accounts of the "beginning of the world" be telling us that the changes at this time were more profound than the geologists normally consider? Looking at ancient legends about the beginning of the world it is striking how the same motifs occur time and again: darkness over the face of the oceans; little or no dry land; the low heavens (the firmament) yet to be separated from the earth; a creator or creators usually of remarkably human kind.

Mythologies come down to us in garbled form; and modern science knows less than it cares to admit. So the split on this issue is difficult to understand.

There is a geological theory with a great deal of evidence in its favour that, in outline at least, can explain the drastic world changes alluded to in ancient legend. But for some reason it has little or no currency: for this reason one hesitates to elaborate

R.B. TOPHAM

Abingdon, Oxon, UK

SIR — It seems to me that creationist science is at least as good as the evolutionary theology propagated by Jon Marks (Nature 28 January, p.276). To take his points in order: the Hebrew used in Leviticus 11: 19 and translated "bird" clearly denotes all warm blooded flying animals since the distinction between birds and mammals was unknown when it was written: Jesus did not ascend to paradise (or heaven) 3 days later as Marks claims. He ascended to heaven bodily at Pentecost 40 days later; what Jesus meant in Luke 23:43 was that both the thief and He would that day be in heaven in their spirits or souls. What Origen and Maimonides thought about the Bible is not pertinent; they were human and could err. There is no doubt, however, that Jesus Christ believed in a 6-day creation, a literal Adam, a real Garden of Eden, an actual world-wide flood and a real whale that swallowed and regurgitated Jonah.

As for the morality of the Bible, neither the rape of Dinah nor the seduction of Lot by his daughters is held up as a good thing. Rather they are consequences of the fall of Man, just as Dr Marks' cynical unbelief is. The execution of Sisera was surely justified for war crimes; he had oppressed Israel harshly for 20 years (Judges 4:3). We do not know all the details but no doubt there was something particularly appropriate that he should be killed by a woman with a tent peg. If Dr

Marks read his Bible with understanding he would realize that Ecclesiastes 3:9 is a perfect description of the futility of man without God, and one that fits Dr Marks himself.

It may be that someone who knows nothing but the 750,000 species of insects is a colossal bore, but someone who knows that, understands every language known to man, comprehends the whole of mathematics, physics and even anthropology would probably consider Dr Marks and his petulant fist waving at his Creator a little boring.

That chimpanzees and humans should be so similar genetically merely shows their Designer recognized a good thing when He saw it.

For Dr Marks to accuse creationists of fraud is a little thick. For whose benefit was the Piltdown fraud perpetrated? What about Haeckel's faked photographs showing that embryology recapitulates phylogeny?

As for obscurantism; the word means the denying of inquiry. Is it not the evolutionists who hold that the theory of evolution is unchallengeable and must be accepted as fact?

T.J. HAMBLIN

Royal Victoria Hospital, Bournemouth, UK

Culture conscious

Sir — In a recent issue (*Nature* **294**, 42; 1981) Adrienne Zihlman reviewed Sarah Hrdy's The Woman That Never Evolved and my own The Evolution of Love.

Professor Zihlman concluded that "Both of these books join the growing stacks of sociobiological attempts to integrate genes and human behaviour. They fail by ignoring the intervening levels. . ." and that "the book that has not yet been written is one that. . . integrates culture and biology". In fact my second chapter contains an elaboration of the interaction of cultural and biological evolution, and my view that cultural evolution has probably "initiated or promoted in humans a far greater number of new behavioural trends than biological evolution has". My index shows that cultural evolution is discussed or mentioned significantly on at least 46 pages of the total of 291 pages of text. SYDNEY L. W. MELLEN

Vevey, Switzerland

SIR - In her review of my book The Woman That Never Evolved, Adrienne Zihlman quotes me out of context and implies that I state women's sexual activity is "assertive and temporarily insatiable". But I was referring to a monkey in oestrus, and was contrasting such monkeys with human females. I wrote: ' what earthly relevance does the conduct of this monkey have for understanding her culturebearing cousin, whose solicitations are sedate. self-conscious, often elaborate in their subtlety and indirection?" (p.160).

My point was to show that cultural practices such as purdah and clitoridectomy, institutions such as marriage, and perhaps especially the myths and values that are a very real component of each human individual, have profound effects on the sexual behaviour of women (pp.179-187).

NEWS AND VIEWS

Creation, evolution and high school texts

from Robert M. May

ANYONE who has seen Clarence Darrow—as played by Spencer Tracy—triumph over William Jennings Bryan in the powerful movie *Inherit The Wind* will be pardoned for thinking that the Scopes Trial helped establish evolution over creation in the United States in the 1920s. This impression is, indeed, fairly widely held, and is explicitly affirmed in at least one university-level biology text.

To the contrary, Grabiner and Miller¹ have shown that the pressures exerted by fundamentalists in the 1920s were successful in bringing about the systematic removal of references to evolution and Darwin in high school biology texts, particularly in the Southern States. Before the Scopes Trial in 1925, several of the widely used texts discussed evolution1: Hunter's A Civic Biology (American Book, 1914), from which Scopes himself taught, had a three page section on evolution together with other associated material elsewhere in the book; Gruenberg's Elementary Biology (Ginn, 1924) was outspokenly evolutionist, with several chapters devoted to the subject and classification discussed from an evolutionary standpoint; Moon's Biology for Beginners (Holt, 1921) had several chapters on evolution and a picture of Darwin as the frontispiece. Other successful texts were more reticent: Smallwood, Reveley and Bailey's New Biology (Allyn and Bacon, 1924), possibly the most widely adopted text of the time, gave about two pages to evolution and omitted any discussion of the origins of man; Clement's Living Things (Iroquois, 1924) gave evolution only brief mention; and Peabody and Hunt's Biology and Human Welfare (Macmillan, 1924) explicitly excluded evolution. Grabiner and Miller give a simple rule for identifying texts published in the decade following 1925: "Merely look up the word 'evolution' in the index or the glossary; you almost certainly will not find it". Concerned about the effect the Scopes Trial might have on sales of his text, Hunter rechristened the 1926 edition New Civic Biology and removed most of the explicit discussion of evolutionary ideas; the word 'evolution' is no longer in the index. The 1926 edition of Moon's Biology for Beginners has the frontispiece portrait of Darwin replaced by a cartoon diagram of the digestive system, although the substantial treatment of evolution in the

text is retained and 'evolution' remains in the index (at last disappearing, however, in the 1933 edition). The treatment of evolution in Smallwood et al.'s New General Biology (1929) is even more perfunctory than in their earlier New Biology, and again the entry for 'evolution' is removed from the index. The most widely used text in the 1930s was Baker and Mills' Dynamic Biology (Rand McNally, 1933), which discusses evolutionary ideas in the final chapter; the book², however, manages to avoid ever using the term 'evolution' and concludes with the extraordinary statement that "Darwin's theory, like that of Lamarck, is no longer generally accepted'

As emphasized by Simpson³, it is not so much that the Scopes Trial precipitated these changes, but rather that both the trial and the changes were consequences of the upsurge of anti-intellectual conservatism and biblical literalism during the period in question. The essential point, however, is that evolutionary biologists were deluded in seeing the drama enacted in the Tennesee courthouse as a significant victory. The real battles were being fought over state and local decisions about which textbooks to adopt for high school biology courses, and here creationists advanced on a broad front throughout the 1920s and 1930s.

We would do well to keep these facts in mind today. Even as the community of professional biologists takes comfort from Judge Overton's incisive and unequivocal verdict against the state of Arkansas' law mandating equal time for 'creation science' in the biology classroom, there are signs that new editions of major high school biology texts are being eviscerated.

As stressed by Nelkin⁴, a sociologist whose Science Textbook Controversies and the Politics of Equal Time (MIT Press, 1977) is the canonical book on this general subject, it is "too early to get a detailed reading on actual changes; they are just being implemented and publishers won't talk". But there are some clear signs, summarized recently by Zuidema⁵. The index to the 1973 edition of Biology: Living Systems (Charles Merrill) gave 17 lines of page references under the heading

'evolution'; in the 1979 edition, 'evolution' is indexed in 3 lines. Recent editions of three Harcourt Brace series texts omit all mention of Charles Darwin, and one excludes the index entry 'evolution' (though the subject is covered in the text). This is sad, as Simpson³ has praised Harcourt Brace for 'consistently and effectively oppos[ing] anti-evolutionist pressure' in the earlier period around 1930–1960. Another brief survey⁶ shows the 1977 edition of an Otto and Towle high school biology text has diminished the coverage of evolution by one-third compared with the 1973 edition.

Taking a different tack, some texts now include material on the Genesis account of creation, or on creation myths generally^{5,6}. Books in which special creation now appears include two editions of Biology: An Inquiry Into the Nature of Life published by Allyn and Bacon in 1974 and 1977, a 1974 Smallwood and Green text, and the 1980 Houghton Mifflin text Biology: The Science of Life. These books can be characterized as teaching about creationism, but not supporting it. More controversial is Biology: A Search for Order in Complexity (Zondervan), written by Moore who is a 'born again' professor of natural science at Michigan State University and a founder of the Creation Research Society. The book was chosen as one of seven officially approved biology texts by the Indiana State textbook commission in 1975, and in two of Indiana's districts was the only ninth-grade biology text available to students. Later, in 1977, the book was barred from use in public schools in Indiana as sectarian; it was relegated to library use as a reference work in Texas, but remains approved by state commissions in Alabama, Georgia, Oklahoma and Oregon5.

Underlying much of this is the system whereby 19 of the 50 United States have prescribed selection systems under which textbooks are approved for adoption in schools. According to rules which vary from state to state among these 'adoption states', one or several books may be approved for school use at a given level?. These texts may then be provided to schools, paid for with tax dollars; alternative books may be used but they must be bought by the individual schools or by individual students. These 19 'adoption states' are preponderantly southern, but importantly include

Robert M. May is Class of 1877 Professor of Zoology at Princeton University, New Jersey 08544. California (which accounts for about 10 per cent of the national textbook market) and Texas (which currently has an annual budget of \$45 million for high school textbooks)7. Given the highly competitive nature of the textbook market, the pressures that this system — with all its political and populist overtones — puts on publishers is obvious. Typical, and understandable, is the havering of one publisher about his company's text8: 'evolution runs like a thread throughout, but is mentioned specifically only in the last chapter".

Why are creationists not a force in Europe? The reasons are many and varied, but one simple set of numbers helps to characterize the difference. Writing of "revived dogma and new cult", Martin9 observes that in Northern Europe, around three to five per cent of those nominally Protestant are found in church on any given Sunday. In contrast, the latest Gallup polls show 51 per cent of all American teenagers in church on any given Sunday and at least one-third of these are fundamentalists.

Grabiner and Miller's conclusions1

about the Scopes Trial era have a message for today. "Readers may choose their own villain in the story we have told. Like us. some will find the greatest culpability in the scientific community itself, for the largescale failure to pay attention to the teaching of science in the high schools. Others will blame the textbook authors and publishers for pursuing sales rather than quality. Some will attach blame to the politicians who exploited anti-evolution sentiment to get into, or remain, in office . . . But whatever the lesson one wishes to draw from the history of biology textbooks since the Scopes trial, we think the story itself is worth knowing. That the textbooks could have downgraded their treatment of evolution with almost nobody noticing is the greatest tragedy of all."

VELOCITY OF LIGHT TO BE CONSTANT — OFFICIAL

from Bridget Marx

ANYONE wanting to measure the speed of light had better do it soon. Indeed, it may already be too late. From the autumn of 1983 no one will be able to follow the example set by such illustrious people as Fizeau, Foucault, Maxwell and Michelson. Why is this? If the proposed new definition of the metre is put forward to and accepted by the General Conference on Weights and Measures, then it will entail the introduction of a fixed numerical value, 299,722,458 m s⁻¹, for the speed of light. Then 'c' will no longer be a measurable quantity but will be a fixed number.

The present situation is as follows. We have the second, the unit of time, defined in terms of a transition frequency near 9 GHz from a caesium atom: the second is the duration of 9,192,631,700 periods of this radiation. We have the metre, the unit of length, defined in terms of a transition wavelength at 605.8 nm from a krypton atom: the metre is 1,650,763.73 times the vacuum wavelength of this radiation.

Using these two defined units, we can measure the speed of light, in metres per second, in one of several ways. The earlier investigators used the technique of actually timing a pulse of light travelling over a measured distance. But light travels so fast that this is a difficult technique to use at high precision. More recently, accurate measurements of c have been made by

using the relationship between frequency, ν , and wavelength, λ , which holds true for all electromagnetic radiation: $v = c/\lambda$.

An accurate measurement of ν , in inverse seconds, and λ , in metres, results in an accurate experimental value of c. One difficulty is that the second and the metre are defined in terms of radiations at very different parts of the electromagnetic spectrum. These measurements therefore involve 'frequency-chains' from the 9 GHz Cs frequency to the 4.95 × 105 GHz Kr frequency - a series of oscillators the outputs of which form bridges to span the spectrum, so that frequencies in the optical region can be compared with those in the radiofrequency region. So for one particular radiation source, usually a laser, the frequency and wavelength can be found by comparison with those quantities which define the units of time and length, giving a precise experimental value of c.

What limits the precision of such an experiment? It is partly determined by how well you can do it, but also by the limiting accuracy with which the basic units can be realized. That is, it depends on how well Cs clocks and Kr lamps can be reproduced internationally, and their frequency and

Bridget Marx is at Coherent (UK) Ltd, Cambridge Science Park, Milton Road, Cambridge CB4 4BH.

wavelength respectively measured. The realization of the second through the Cs clock has a reproducibility of better than 1 part in 1013. Despite the fact that wavelength comparisons can be made at an accuracy of parts in 1011, the realization of the metre through the Kr lamp, which has a relatively broad spectral profile, is reproducible only to about 4 parts in 10°. As saturated absorption-stabilized lasers operating in the visible are internationally reproducible to a few parts in 1011, there is obviously scope for an improved definition of the metre.

From what has been said, it might seem that a good redefinition of the metre would be to specify it, as at present, in terms of a wavelength, but to choose as this wavelength the most accurate that can be generated with a visible laser source. (For practical reasons it is easiest to use visible radiation for length measurement.) This would indeed be possible, but it would not be easy to decide which laser would be best for the definition. It would also mean that if a better, more accurate laser became available in a few years, then the definition might need to be changed again. It has therefore been decided to use the high precision of the frequency standard and to define the metre in terms of the second and a fixed value for the speed of light. The redefinition most likely to be recommended is that "the metre is the length equal to the distance travelled in a time interval of 1/299,792,458 of a second by plane electromagnetic waves in a vacuum" (Comité Consultatif pour la Definition du Metre BIPM, 6th session, Sèvres; 1979). In this definition, c becomes simply a conversion factor between time and length.

This is a concept that we are familiar with through the use of the 'light year' as a unit of length. Both the proposed definition and the light year assume that the speed of light is constant but, as has been pointed out earlier (W. R. C. Rowley, Phys. Bull. 31, 334;1980), the constancy of c is also assumed implicitly in the present definition of the metre. What is fixed in the krypton atom is its energy level structure, and so the transition energy E. The wavelength emitted from the transition is given by $\lambda = hc/E$, where h is Planck's constant. The value of c to be used in the new definition has been chosen to be that measured with the existing metre, so that continuity is maintained.

The proposed redefinition of the metre will, however, rely heavily on laser sources for its realization. Any radiation of known frequency will automatically be of known wavelength, because c is fixed, and so may be used as a wavelength and length standard. And as the reproducibility of the frequency standard is improved, so the accuracy of the metre will follow it which is good news for everybody, except for those who have always wanted to measure the speed of light but haven't got round to it yet.

Gravity waves seeding ionospheric irregularities

from Jürgen Röttger

THE upper atmosphere of the Earth, particularly above 50 km altitude, is partly ionized by solar radiation. The electron densities that result display diurnal, seasonal and other quasi-regular variations, the peak densities occurring within the so-called F-region of the ionosphere (see Fig. 1). Superimposed on these comparatively predictable features of ionospheric behaviour are disturbances such as those caused by solar flares and magnetospheric storms. Other irregularities, detectable by means of radio waves reflected or scattered from the ionosphere and unrelated to any obvious extraterrestrial disturbance, are often difficult to explain. However, recent work has demonstrated that the neutral atmosphere plays a crucial role in their generation.

Their usual name apart, irregularities in the ionospheric plasma are rather common and regular features. Particularly near the equator, F-region irregularities occur quite frequently during the night and often exhibit a rather ordered, even periodical occurrence1,2. Various plasma instabilities are responsible for generating irregularities with dimensions less than a few kilometres3 while dynamic processes in the neutral atmosphere are responsible for larger-scale periodical features of equatorial F-region irregularities1-5. These processes are internal gravity waves which cause travelling ionospheric disturbances (TIDs) in the ionized part of the upper atmosphere. Recent research has shown that the disturbances can be amplified in the equatorial F-region due to mutual coupling with dynamic processes in the ionospheric plasma6. The resulting phenomena are periodic modulations, wave breaking as well as seeding or triggering plume-like irregularities.

Understanding of the equatorial F-region plasma irregularities has advanced in the present decade by the combination of theory and numerical simulations with data from ionosondes, backscatter radars, rockets and satellites and from analyses of scintillations of satellite signals1-3. The irregularities, which are also called 'equatorial spread-F', commence after the bottomside profile of the post-sunset F-layer has steepened. Steep vertical gradients of plasma density can be unstable to the classic Rayleigh-Taylor instability because a heavy fluid the plasma - is supported against gravity by the Earth's magnetic field. Perturbations in the plasma density of the bottomside F-region develop into density depletions and small-scale irregularities. Irregularities at the bottomside of the ionosphere occur in wave trains of patches

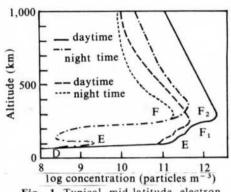

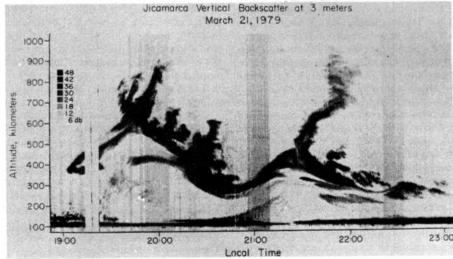

Fig. 1 Typical mid-latitude electron concentration profiles in the ionosphere. The larger daytime and night-time values occur at sunspot maximum, the smaller at sunspot minimum.

separated by some 100 km (ref. 4) and move eastwards and downwards. Plume-like irregularities are caused by the depletions rising, like bubbles in a fluid, to the topside of the F-region^{7,8}.

The new evidence⁶ that gravity waves initiate equatorial spread-F irregularities comes from observations carried out with the Jicamarca radar located close to the magnetic equator near Lima, Peru. The radar transmits at 50 MHz with 1 MW pulse power from a phased-array 300 m × 300 m antenna pointing nearly vertically. Backscattering from field-aligned spread-F irregularities of scale sizes of one-half the radar wavelength can be observed and radar pictures of the life history of spread-F irregularities recorded7,9,10. One spectacular event recorded by Kelley et al.6 is shown in Fig. 2. The irregularities first occurred after sunset at the bottomside of the F-layer and, during the evening, the bottomside irregularities underwent nearly two full cycles of a quasi-periodic vertical motion. In both cycles, distinct plume-like structures extended to the topside of the F-laver and during downward motion, plumes were generated at intervals of about 20 min. These plumes are the signatures of plasma bubbles rising through the ionosphere up to altitudes of about 1,000 km. Because of their alignment to the Earth's magnetic field, the bubbles extend in stretched tubes to the north and south of the magnetic equator.

Since magnetospheric influences on the periodic bottomside modulation of the irregularity pattern can be ruled out, Kelley et al.6 argued that gravity waves have a role in this process in agreement with earlier investigations relating internal gravity waves to equatorial spread-F4,5,11,12. This relation is rather intriguing since it allows a spatial resonance mechanism, as proposed by Whitehead13, to play a part - most effectively in the post-sunset equatorial F-region where the ionospheric plasma, drifting downwards at some 10 m s-1, has similar downward phase velocities to those of gravity waves. An eastward plasma drift of 100-200 m s-1 is also observed14,15, matching typical horizontal phase velocities of gravity waves. When this matching occurs, the ionization pattern due to the wave stays in the same position relative to a drifting ionization parcel, and the wave-like perturbation in the ionization consequently increases. Even very small disturbances can be strongly amplified by this resonance and can reach the non-linear regime¹². Steep ionization gradients and depletions appear as a consequence. These were assumed to be the periodic source regions, that is, the primary perturbations necessary to initiate the Rayleigh-Taylor instability at the bottomside F-layer4,12. As observed with radars, the generated ionization depletions or bubbles then drift upwards to the peak and the topside of the ionosphere^{7,8}. Independent of the radar observations, deep depletions (bite-outs with only some per cent density of the surrounding plasma) were detected by in situ measurements with rockets and

Fig. 2 Radar map showing echo traces due to backscatter from equatorial spread-F irregularities at altitudes larger than 200 km.

Jürgen Röttger is at the Max-Planck-Institut für Aeronomie, 3411 Katlenburg-Lindau, FRG. satellites2,16. The periodic features of spread-F plumes or bubbles also cause intense scintillation of satellite signals¹⁷ and adversely affect radio communication links.

Including the Doppler effect due to neutral background winds, Kelley et al.6 discussed the range of gravity waves which could match their data. They found that the long-period huge ionization perturbation observed in Fig. 2 would require a vertical velocity amplitude of 100 m s⁻¹ much too large to be realistic. They concluded that a gravity wave itself cannot explain the magnitude of disturbance but seeds the initial perturbations even if spatial resonance is only partially attained. Provided an initial finite amplitude perturbation exists due to gravity waves, they assumed that a nonlinear Rayleigh-Taylor growth for long-wavelength structures can be sufficiently high to explain the long-period modulation in Fig. 2. Smaller disturbances, with shorter periods of about 20 min, occurred during the downward motion and may be due to shorter-period gravity waves superimposed on the long-period perturbation.

These recent results establish that the life history of equatorial spread-F irregularities is a multistep process, starting with initial large-scale perturbations due to gravity waves which seed the generation by plasma instabilities of a cascade of smaller-scale

irregularities. As shown for the equatorial region, processes in the ionosphere cannot solely be treated from the viewpoint of plasma physics, but neutral atmosphere processes, namely internal gravity waves. have to be regarded as well. Since these waves presumably are generated in the troposphere^{6,18}, intriguing research on the coupling between the lower and upper atmosphere remains for the future.

Molecular basis of growth hormone deficiency

from Mike Wallis

THE first use of recombinant DNA technology to investigate the molecular basis of defective production of pituitary growth hormone (GH), one of the causes of dwarfism in man, is described in a recent paper by Phillips, Hjelle, Seeburg and Zachmann¹. Three related Swiss families were studied. The growth hormone deficiency is inherited2 in an autosomal recessive mode; the six parents had normal stature but the growth of four of nine children was stunted. Using a cloned cDNA probe for human growth hormone (hGH), Phillips et al. showed that each of the four stunted individuals was homozygous for a deletion of at least 7.5 kilobases of DNA which includes most, or perhaps all, of the normal human growth hormone gene sequence. The dwarf individuals show a complete lack of GH (but not of other pituitary hormones) and when treated by the administration of hGH develop antibodies which neutralize its effect.

Phillips et al. took high molecular weight DNA prepared from blood samples from the dwarfs, other members of the same families and from control (unrelated) indi-

viduals and digested it with a variety of restriction endonucleases. The DNA digests were fractionated by electrophoresis, transferred to nitrocellulose filters (Southern blotting) and hybridized with a labelled hGH cDNA probe. For each restriction enzyme digest, several hybridizing bands were detected corresponding to various members of the family of genes known to be related to cDNA for hGH3. In each case, the affected (GH-deficient) individuals lacked one of the hybridizing bands, and their parents and most (but not all) of their siblings possessed less of this component (as would be expected for heterozygotes) than did normal individuals.

Interpretation of the data is complicated by the presence of at least two types of hGH gene (hGH-N and hGH-V; normal and variant) and probably at least three types of gene for the closely related hormone placental lactogen. The DNA sequence(s) coding for the placental lactogen are suffi-

Mike Wallis is in the School of Biological Sciences at The University of Sussex, Falmer, Brighton, Sussex BN1 9QG.

ciently similar to those for hGH for extensive cross-hybridization to occur. Phillips et al. detected DNA fragments corresponding to at least the two hGH genes (hGH-N and hGH-V) and one placental lactogen gene, and their observations were apparently complicated further by the existence of an allelic polymorphism occurring in a placental lactogen gene. Their work suggests that the hGH-N and hGH-V genes are non-allelic, and that the hGH-V gene (which could produce a growth hormone differing from normal hGH at about 14 residues) is either nonfunctional or produces a poorly functional product in the GH-deficient individuals, all of which retain this gene. It is still possible, however, that the hGH-V gene is expressed and functional in normal individuals: deletion of DNA associated with the hGH-N gene in the dwarfs might lead to reduced expression of the hGH-V gene.

The complexity of the organization of the human GH and placental lactogen gene family contrasts with the situation in nonprimate mammals. In the rat, for example, cDNA to rat GH cross-hybridizes with only a single growth hormone gene, the structure of which has been elucidated in detail⁴⁻⁶. The gene contains four introns. The related protein hormone prolactin is also represented by a single gene in the rat genome^{4,7}; again, the gene contains four introns, the positions of which correspond to those in growth hormone, but the sizes of which are far greater (on the average by a factor of five). It seems likely that the genes of the hGH-human placental lactogen family underwent a period of rapid evolution, including gene duplication and multiple substitutions, during the evolution of the primates; not only does the organization of the genes for GH-like proteins in primates differ markedly from that in non-primates, but the amino acid sequences of hGH and non-primate GHs are also very different8.

The kind of approach used by Phillips et al.2 should be applicable to the investigation of other types of hGH deficiency. Much human dwarfism, however, does not result from simple lack of GH. Other causes of short stature are recognized, but many children are very short despite normal immunoreactive GH levels and the absence of any other obvious cause. Recently, Rudman et al.9,10 have proposed that a substantial proportion of such 'normal-variant short stature' (NVSS) children are short because they have a defective GH, which is still detectable by radioimmunoassay. Growth may be inducible in such children by exogenous GH. This work has aroused great interest in the medical journals, though some aspects of it remain controversial¹¹⁻¹³. Application of recombinant DNA techniques should help elucidate the nature of such GH defects.

Dwarfism caused by lack of GH can often be treated by injection of hGH (but not non-primate GH) and such treatment

has been applied effectively in the UK and many other countries using GH extracted from human pituitary glands. The supply has barely met the demand, however, and recently increasing demand and falling supplies have aggravated the situation (see Nature News 294, 200; 1981). Application of recombinant DNA technology has led to the production of hGH from bacteria^{14,15}, and clinical trials with such material are starting. If the prevalence of GH-treatable NVSS children is as high as Rudman and his colleagues suggest (perhaps two to ten times as many as those now treated with GH), the need for hGH produced by genetic engineering will be considerable. But the hGH produced in bacteria is unlikely to be completely without problems. The material currently being tested has a structure slightly different (due to an additional N-terminal methionine residue) from the pituitary-derived hormone, and there is no guarantee that bacterially derived material will be substantially less expensive than that obtained from pituitaries. (Complete treatment of a GH-deficient child currently costs about £10,000.)

St Patrick and the bacteria

from J.S. Jones

THERE are two models of the absence of snakes from Ireland, neither of which, as the Creationists delight in reminding us, is directly testable. The older of these has it that St Patrick banished into the sea all manner of noxious and creeping things from his adopted land. More recent theories - such as MacArthur and Wilson's equilibrium theory of insular biogeography¹ — see this absence as a result of the unique faunal history of islands, which is profoundly influenced by their size and isolation.

The classic studies in island biogeography have been of birds but, surprisingly, more direct opportunities to test McArthur and Wilson's theory are now coming from investigations of the patterns of bacterial and viral infections in man. Not only does it appear that the spread of disease in isolated islands of human population accords well with the theories of biogeographers, but even changes in the bacterial flora of a single individual and an 'archipelago' of his family, friends and pets follows the same ecological rules as those thought to control the biology of island birds.

The equilibrium theory of island biogeography

attempts to predict the number of species on an island from a balance between immigration and extinction. Immigration depends largely on the island's distance from a mainland source. The rate of extinction is related to the island's area; the smaller the island, the fewer the members

The MacArthur and Wilson theory

of a particular species which it can support and the greater the chance that the species will become extinct through random fluctuations in population size. Considerable turnover will thus be expected; although the number of species on an island will be constant, their identity will change with time, with the accidents of immigration and extinction leading to a dynamic equilibrium.

In an important new book, Williamson² takes a critical look at some of the many attempts which have been made to interpret the biology of islands in terms of the equilibrium theory. He points out that although it has been known for more than a century that there is a relationship between the number of species and an island's area and isolation, the evidence for a constant random turnover on islands is much less convincing. A forty year study of the birds of Skokholm, for example, shows that there has been almost no species turnover during this period. Other claims3 that the population history of island birds in the Pacific and elsewhere supports the McArthur-Wilson view of species turnover on very inadequate are based information4.

Can more adequate data be taken from the huge body of information on the ecology of infectious disease? If infection is regarded as the immigration of a disease and cure as it's extinction then it seems that it may.

Humans on islands

Measles occurs only in man and, because immunity follows infection, the virus can persist only in a large population where there is a continuous supply of susceptible persons⁵. A study of 19 island populations⁶ shows that measles periodically dies out in

all those containing less than 500,000 people, and that (exactly as claimed by MacArthur and Wilson) the probability of extinction of the virus is greater on small islands than on large. The rate of immigration also has a major effect on persistence and turnover; in Iceland (where records of the incidence of measles date from 1869), there were intervals of up to seven years between epidemics before 1938, a period during which there was little movement of infected individuals into the island. After 1945, when immigration was common, the time between epidemics was never more than two years7.

A similar pattern of turn over has been traced in an isolated Eskimo village from the persistence of specific antibodies in those who survived polio infection8. One strain passed through the community 25 years before the investigation; another 15 years before, and a third only within the previous year.

Black9 points out that most primitive human communities exist as islands of population, and that many of their diseases show such patterns of turnover, with a balance between the immigration and extinction of pathogens which is related to each island's size and isolation. In Amazonian tribes, for example, the incidence of particular infectious diseases differs greatly (and apparently at random) between the various isolated communities. In different villages the proportion of the population with antibodies to measles varies from 0 to 98 per cent, to rubella from 0 to 95 per cent and to parainfluenza B from 0 to 89 per cent. Disease incidence again results from a dynamic equilibrium between a chance immigration and a period of persistence followed by extinction.

Humans as islands

To bacteria, all men are islands, safe refuges in an inhospitable sea. The human intestine is such a favourable habitat that every healthy individual has ten times as many symbiotic bacterial cells as he has cells of his own11. Gel electrophoresis of a sample of enzyme loci makes it possible to detect individual strains of bacteria and provides a new and intriguing chance to study the island biogeography of man. Isolates of Escherischia coli from humans, water supplies and laboratory stocks are made up of a great number of genetically distinct and persistent clones, each of which has a unique enzyme profile12. Gene exchange among clones is a very rare event¹³ so that E. coli is in some senses a complex of a very large number of genetically well differentiated 'species' that can be identified using biochemical markers. One clone, found in 1979 in a Massachusetts infant, is identical to the laboratory strain K12, first isolated 50 years ago.

Caugant et al. 14 have studied the ecology of such clones (or species) within a Dr Bruce Levin of the University of Massachusetts. Over eleven months (which represents thousands of bacterial gener-

J.S. Jones is in the Department of Genetics and Biometry, University College London, Gower Street, London WCIE 6BT.

ations) this human 'island' supported a fauna of 53 clones. Most were transient. and appeared on only one sampling occasion but one persisted for several months and two others occurred for most of the period of observation.

The E. coli clones therefore showed considerable 'species' turnover although the actual number of clones remained fairly constant. New clones probably arrived by immigration from the food as the nearby islands in the Levin Archipelago (the two Doctors Levin, their children and their cat) shared a similar array of clones. Clones were lost by random extinction. These observations further support the view that the species composition of islands involves considerable flux.

Biogeography and disease

Other useful analogies may be drawn between the biology of island birds and that of human pathogens. For example, islands such as the Galapagos - are uniquely favourable in promoting the origin of new bird species. It is possible that the evolution of new pathogens takes place primarily in highly sub-divided human populations and that the recent expansion of mankind to form a single large continental mass with

free interchange among its parts has greatly retarded the evolution of new disease organisms.

Birds on isolated islands with few competing species and slow species turnover have habitat preferences quite different from mainland populations². The ecology of pathogens in isolated human populations might also differ from that in modern cities.

After defaunation by volcanic explosions or poison gas, islands show changes in the diversity, turnover and ecology of their inhabitants^{17,18}; the return to equilibrium may be long delayed. Recolonization of a human host after antibiotic treatment could lead to similar and unexpected changes in the ecology of the pathogens which remain.

The most recent models of island biogeography use differences in the efficiency of migration and resource utilization of individual species to predict the species composition of birds on islands¹⁹. Clones of E. coli also differ greatly from each other in their ability to utilize resources²⁰. Developments in theories of island biogeography may therefore help to explain why some clones

are resident and some transient in the intestine¹⁴, and why certain pathogens (such as hepatitis B or herpes virus) are present in all human populations including those on islands — while others occur only sporadically8. It is even possible that such developments may help to eliminate pathogens by means of the secular miracles of medicine rather than the direct intervention of a saint.

100 YEARS AGO

ON THE CONSERVATION OF SOLAR ENERGY¹

The question of the maintenance of Solar Energy is one that has been looked upon with deep interest by astronomers and physicists from the time of La Place downwards

The amount of heat radiated from the sun has been approximately computed by the aid of the pyrheliometer of Pouillet and by the actinometers of Herschel and others at 18,000,000 of heat units from every square foot of its surface per hour, or, put popularly, as equal to the heat that would be produced by the perfect combustion every thirty-six hours of a mass of coal of specific gravity = 1.5 as great as that of our earth.

If the sun were surrounded by a solid sphere of a radius equal to the mean distance of the sun from the earth (95,000,000 of miles), the whole of this prodigious amount of heat would be intercepted: but considering that the earth's apparent diameter as seen from the sun is only seventeen seconds, the earth can intercept only the 2,250-millionth part. Assuming that the other planetary bodies swell the amount of intercepted heat by ten times this amount, there remains the important fact that $\frac{24999999}{225000000}$ of the solar energy is radiated into

¹ Paper read at the Royal Society, March 2, by C. William Siemens, D.C.L., L.L.D., F.R.S., Mem. Inst. C.E.

space, and apparently lost to the solar system, and only $\frac{1}{2.250000000}$ utilised.

Notwithstanding this enormous loss of heat, solar temperature has not diminished sensibly for centuries, if we neglect the periodic changes, apparently connected with the appearance of sun-spots that have been observed by Lockyer and others, and the question forces itself upon us how this great loss can be sustained without producing an observable diminution of solar temperature even within a human lifetime.

Amongst the ingenious hypotheses intended to account for a continuance of solar heat is that of shrinkage, or gradual reduction of the sun's volume suggested by Helmholtz. It may, however, be urged against this theory that the heat so produced would be liberated throughout its mass; and would have to be brought to the surface by conduction, aided perhaps by convection; but we know of no material of sufficient conductivity to transmit anything approaching the amount of heat lost by radiation.

Chemical action between the constituent parts of the sun has also been suggested; but here again we are met by the difficulty that the products of such combination would ere this have accumulated on the surface, and would have formed a barrier against further action.

These difficulties have led Sir Wm. Thomson, following up Mayer's speculation, to the suggestion that the cause of the maintenance of solar temperature might be found in the circumstance of meteorolites falling upon the sun from great distances in space, or with an acquired velocity due to such fall, and he shows that each pound of matter so imported would represent a large number of heat units depending upon the original distance. Yet the aggregate of material that would thus have to be incorporated with the

sun would tend to disturb the planetary equilibrium, and must ere this have shortened our year to an extent exceeding that resulting from astronomical records and observation. In fact, Sir William Thomson soon abandoned the meteoric hypothesis for that of simple transfer of heat from the interior of a liquid sun to the surface by means of convection currents, which latter hypothesis appears at the present time to be supported by Prof. Stokes and other leading physicists of the day.

But if either of these hypotheses could be proved we should only have the satisfaction of knowing that the solar waste of energy by dissipation into space was not dependent entirely upon loss of its sensible heat, but that its existence as a luminary would be prolonged by calling into requisition a limited, though may be large, store of energy in the form of separated matter. The true solution of the problem will be furnished by a theory, according to which the radiant energy which is now supposed to be dissipated into space and irrecoverably lost to our solar system, could be arrested and brought back in another form to the sun itself, there to continue the work of solar radiation.

CAN Mr Wallace throw any light on Mr Allen's somewhat extraordinary sentence: "I feel a genuine respect for every donkey I meet. when I remember that it was the mere accidental possession of an opposable thumb that gave my ancestors a start over his in the race for the inheritance of the earth towards the very close of the tertiary period." I take Mr Allen to be an evolutionist, but there is no place for accident in evolution, or in any other scientific theory. The "opposable thumb" must be the result of some conditioning factor, and this being so the word accident is quite out

REVIEW ARTICLE

Molecular mechanisms of variation in influenza viruses

R. G. Webster', W. G. Laver', G. M. Air' & G. C. Schild[‡]

* St Jude Children's Research Hospital, Memphis, Tennessee 38101, USA
† The John Curtin School of Medical Research, Australian National University, Canberra, ACT 2601, Australia
‡ National Institute for Biological Standards and Control, London NW3 6RB, UK

Influenza is unique among the viruses in its capacity to vary. Because of antigenic variation, it has proved impossible to control influenza by vaccination, and variation in virulence, host range and transmissibility influence the spread and severity of influenza epidemics. This variation is caused by sequence changes in the genes of the virus and this review summarizes recent information on the structure of the genes and their products, the way in which these vary and the effects of the changes on the biological activities of the virus.

OVER the past decade influenza epidemics have been relatively mild, causing only modest increases in morbidity and mortality. However, the potential of the influenza virus as a major and unpredictable threat to public health is highlighted by historic events. During the weeks from 19 October 1918 to the end of February 1919, an influenza A virus which, from circumstantial evidence, was almost certainly antigenically closely related to 'swine' influenza A virus, killed at least 20 million persons and affected perhaps one hundred times that number. It was without doubt one of the most devastating plagues ever documented. Such an event could happen again.

In 1979-80, ~20% of the harbour seal (*Phoca vitilina*) population of the north-east coast of the United States died of a severe respiratory infection with consolidation of the lungs, typical of primary viral pneumonia¹. Influenza virus particles were found in high concentrations in the lungs and brains of the dead seals. Antigenic analysis showed that this virus was closely related to fowl plague virus (A/FVP/Dutch/27 (H7N7)), a highly lethal influenza virus of chickens not previously found in mammals². What would happen if such an event occurred in man instead of seals? Would the resulting pandemic be similar to that of 1918-19?

Properties of influenza virus

Influenza viruses are classified into three types-A, B and C—on the basis of their type-specific nucleoprotein and matrix protein antigens. Type A influenza viruses are further classified into subtypes based on the antigenic characteristics of their surface antigens, haemagglutinin (HA) and neuraminidase (NA). Twelve distinct HA subtypes and nine NA subtypes are now recognized in the nomenclature system for influenza A viruses recommended by the World Health Organization³, and a thirteenth HA subtype has recently been identified⁴. Examples of the use of this nomenclature system are as follows: A/Hong Kong/68 (H3N2) is an influenza A virus isolated from man in 1968 with HA of subtype H3 and NA of subtype N2, while A/equine/Miami/63 (H3N8) is a virus isolated from horses, with HA of the same subtype as that of the human virus but with a distinct NA antigen. It is implicit in this system that all viruses with common H or N subtype have HA or NA antigens shown to be related by conventional laboratory tests (such as double immunodiffusion) while such relationships do not occur between subtypes. However, included among viruses of a common subtype designation will be strains showing considerable degrees of variation. Thus, the human virus A/Bangkok/1/79 (H3N2) contains HA and NA antigens demonstrably related to those of A/Hong Kong/68 virus but showing considerable degrees of difference from them. During

the present century three distinct subtypes of influenza A virus have caused pandemics in man—the H1N1 subtype which probably appeared in 1918, the H2N2 ('Asian') subtype which appeared in 1957 and the H3N2 ('Hong Kong') subtype which appeared in 1968.

This review will be concerned with type A influenza, which has been responsible for the major pandemics and has been investigated more extensively than types B and C.

The highly pleomorphic particles of influenza virus are enclosed by a lipid envelope, derived from the plasma membrane of the host cell, to which the HA and NA antigens are attached by short sequences of hydrophobic amino acids at one end of the molecules⁵⁻⁷. Both surface antigens are glycosylated and some of the carbohydrate side chains possess antigenic activity characteristic of the host cell in which the virus grew.

Within the lipid envelope lies the matrix protein, which is believed to be structural in function. Within the matrix shell are eight single-stranded RNA molecules of negative sense (that is, the virion RNA is complementary to the messenger RNA) associated with a nucleocapsid protein and three large proteins, P1, P2 and P3, responsible for RNA replication and transcription. At least three virus-encoded non-structural proteins are found in infected cells, but their functions are unknown⁸⁻¹⁰. Table 1 summarizes current information on the eight genes of the influenza virus and the molecular weights (M_r) of the proteins encoded by them.

Variation in haemagglutinin

The HA accounts for about 25% of the virion protein. It is responsible for attachment of the virus to cells and for the stimulation of antibodies that neutralize the virus. The HA monomer is synthesized as a single polypeptide chain which undergoes post-translational cleavage at three places. An N-terminal signal sequence is removed and, depending on the host cell and virus strain, the molecule is cleaved, with the removal of one or more intervening residues, to give two polypeptide chains called HA1 and HA2, with molecular weights of 36,000 and 27,000, respectively (Table 1). A sequence of hydrophobic amino acids near the C-terminus of HA2 serves to anchor the HA in the virus membrane.

The three-dimensional structure of Hong Kong (H3N2) HA has recently been determined¹¹ and it seems likely that HA molecules from other subtypes will have similar structures. The HA glycoprotein of influenza virus is a trimer built of two structurally distinct regions: a triple-stranded coiled-coil of α -helices extend 76 Å from the membrane and a globular region of antiparallel β -sheet that contains the receptor binding site; the variable antigenic determinants are located on top of this

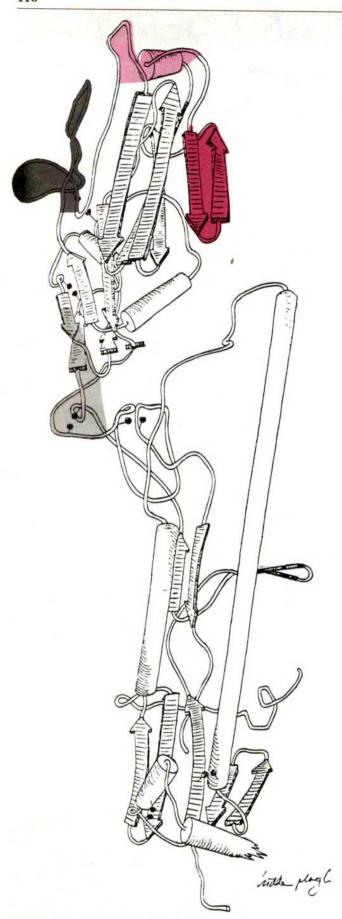

Fig. 1 Drawing (by Hidde Pleogh) of the Hong Kong (H3) HA monomer showing folding of the HA1 and HA2 polypeptides^{11,12}. The four coloured areas show where four independent antigenic areas may be located. Note that in the HA spike, which is composed of three of the monomers, the dark red site is buried and may not be involved in antibody binding.

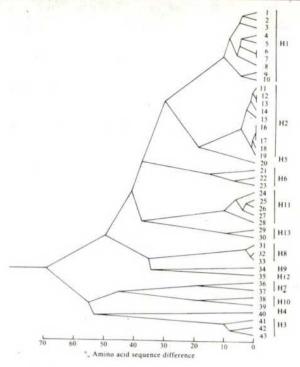

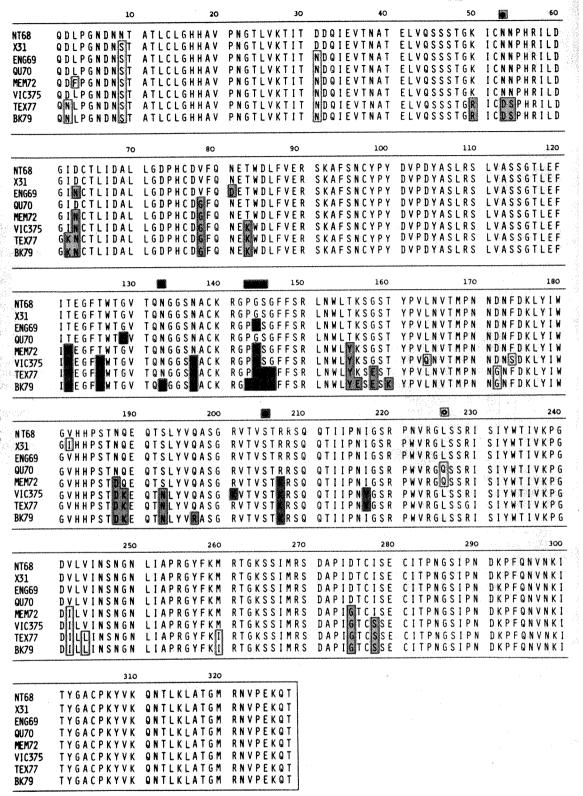

Fig. 2 Dendrogram showing the relationships between the HA1 Nterminal amino acid sequences deduced from genomic sequences of viruses representing the 13 known subtypes. The sequences were aligned using amino acids that are invariable in certain positions of all sequences (amino acid position from N terminus of most subtypes: Cys 4, Gly 6, Thr 18, Val 26, Cys 42, Cys 55, Gly 63, Pro 65, Cys 67, Glu 81). The percentage sequence differences of all pairwise comparisons of the aligned sequences starting from the N-terminal Asp or corresponding amino acid were used to calculate the dendrogram. Thus, the positions of each bifurcation in the dendrogram indicate the mean sequence difference of the sequences connected through that point⁴. The sequences used in the analysis are: 1, A/NWS/33 (H1N1); 2, A/PR/8/34 (H1N1); 3, A/BH/35 (H1N1); 4, A/Bel/42 (H1N1); 5, A/Loyang/4/57 (H1N1); 6, A/USSR/90/77 (H1N1); 7, A/Fort Warren/1/50 (H1N1); 8, A/duck/Alberta/35/76 (H1N1); 9, A/swine/Wisconsin/15/30 (H1N1); 10, A/New Jersey/11/76 11, A/RI-/57 (H2N2); 12, A/Tokyo/3/67 (H2N2); 13, eley/68 (H2N2); 14, A/Netherlands/68 (H2N2); 15, A/duck/GDR/72 (H2N9); 16, A/duck/New York/6750/78 (H2N2); 17, A/duck/Ontario/77 (H2N1); 18, A/duck/Alberta/77/77 (H2N3); 19, A/duck/Ollaino/// (H2N1); 16, A/duck/Alberta///// (H2N3); 17, A/pintail/Alberta/293/77 (H2N9); 20, A/shearwater/Australia/75 (H5N3); 21, A/shearwater/Australia/72 (H6N5); 22, A/duck/Alberta/1298/79 (H6N5); 23, A/duck/Alberta/1297/79 (H6N9); 24, A/tern/Australia/75 (H11N9); 25, A/duck/Ukraine/1/60 (H11N9); 26, A/duck/England/56 (H11N6); 27, A/duck/New (H1N9); 24, A/tern/Australta/75 (H1N9); 25, A/duck/Ukraine/1/60 (H1N9); 26, A/duck/England/56 (H1N6); 27, A/duck/New York/12/78 (H1N6); 28, A/duck/Memphis/576/76 (H1N9); 29, A/gull/Mass/26/80 (H13N6); 30, A/gull/Md/704/77 (H13N6); 31, A/turkey/Ontario/6118/68 (H8N4); 32, A/duck/Alberta/827/78 (H8N4); 33, A/duck/Alberta/283/77 (H8N4); 34, A/turkey/Wisconsin/1/66 (H9N2); 35, A/duck/Alberta/60/76 (H12N5); 36, A/duck/Olara (Table 1) (H12N5); 36, A/duck/Olara (sin/1/66 (H9N2); 35, A/duck/Alberta/60/76 (H12N5); 36, A/turkey/Oregan/71 (H7N3); 37, A/equine/Prague/1/56 (H7N7); 38, A/duck/Manitoba/53 (H10N7); 39, A/quail/Italy/1117/65 (H10N8); 40, A/duck/Alberta/28/76 (H4N6); 41, A/black duck/Australia/702/78 (H3N8); 42, A/Memphis/1/71 (H3N2); 43, A/duck/Ukraine/1/63

stem. Each subunit has an unusual loop-like topology: it begins at the membrane, extends 135 Å distally and folds back to enter the membrane.

Four antigenic sites on the three-dimensional structure of the HA molecule of Hong Kong influenza viruses have been proposed ¹²⁻¹⁴. The suggested locations (Fig. 1) were derived from amino acid sequence changes in antigenic variants of Hong Kong virus selected using monoclonal antibodies ¹⁵ and in natural variants of this virus ^{11,16,17}.

Variation in the HA molecule of influenza viruses occurs in two ways. It is now known that small changes in antigenicity (antigenic drift) are the result of a gradual accumulation of point mutations, while the complete change in antigenic properties (antigenic shift) involves replacement of the gene coding for one HA with that for another; this may or may not be accompanied by replacement of the NA gene.

Fig. 3 Amino acid sequences using the single letter amino acid code of the HA1 polypeptide from eight variants of Hong Kong (H3N2) influenza virus isolated between 1968 and 1979. Data are from refs 17, 21, 25, and B. A. Moss and G Brownlee (unpublished results). Residues which have changed from NT68 are coloured or boxed. The location of most of these changes on the threedimensional structure of the HA are shown in Fig. 1. (Boxed changes were scatthe threetered over dimensional structure and may not affect the antigenic properties of the HA. They have not been shown in Fig. 1.) •, The sequence changes found in selected with variants monoclonal antibodies¹⁵. These are (53) Asn→Lys, Asn → Lys, (143) (133)Pro → Ser, Thr, Leu, His, (144) Gly → Asp, Ser → Lys, (205) Ser → Tyr. The change (226) Leu→ Gln (O) appears to arise with remarkable ease. This change has been found in different clones of the same field strain and in monovariants clonal which already show another may change and he unrelated to changes antigenicity.

Antigenic shift

Since the first human influenza virus was isolated in 1933, antigenic shifts have occurred in 1957 when the H2N2 subtype (Asian influenza') replaced the H1N1 subtype, in 1968 when the Hong Kong (H3N2) virus appeared and in 1977 when the H1N1 virus reappeared. All these major antigenic shifts in the virus occurred in China and anecdotal records suggest that previous epidemics (probably caused by the sudden emergence of 'new' viruses) also had their origin in China. Although we are still uncertain how these new subtypes appear or reappear in the human population, some clues are emerging from the plethora of recent sequence data.

The complete amino acid sequences of HA1 and HA2 have been deduced from the sequences of cloned DNA copies of the genes for strains representative of four different HA subtypes of type A influenza—fowl plague (H7N7) virus¹⁸, Asian (H2N2) influenza virus⁶, PR8 and WSN (H1N1) viruses^{19,20} and a number of strains within the human Hong Kong (H3N2) subtype^{17,21}. A complete protein sequence analysis is available only for the H3 strain^{22,23}, although sufficient protein data are available for the H2 strain to indicate where the signal peptide is removed and where the molecule is cleaved into HA1 and HA2. The data also show the location of the single disulphide bond connecting HA1 and HA2 and that most of the potential

glycosylation sites in the HA do have carbohydrate attached. The complete sequences of two strains of A/Duck/Ukraine/63 (H3N8) haemagglutinin have also been determined, one from gene sequence data²⁴, the other from direct protein sequencing²⁵.

Sequences up to 350 nucleotides from the 3' end of the HA gene and the predicted amino acid sequences from 32 type A influenza viruses, including representatives of each of the 12 known HA subtypes, have been determined²⁶. Cysteine residues and certain other amino acids are conserved in all sequences, indicating that the 12 HA subtypes evolved from a common ancestor and share a common basic structure. When the partial amino acid sequences are compared pairwise, the most distant subtypes are H1 and H3 (25% homology). Other subtypes are more similar to each other, the highest homology (80%) being between H2 and H5. Relationships between the partial sequences can be illustrated as a dendrogram (Fig. 2).

Within strains of a single subtype, the differences in deduced amino acid sequence are generally less than 10% (ref. 26), but recent extensions of the data have revealed differences in the N-terminal region of HA1 from two strains each of H7 and H10 viruses close to 20%, almost equal to the difference between the amino acid sequences of the two closest subtypes (H2 and H5).

Whereas it is possible to imagine that the H2 viruses could eventually mutate into H5, the change to H3 must involve a more drastic mechanism. How, then, could the H3 haemagglutinin have replaced the H2 strain in the human population in 1968? First, the 'new' virus may have caused an epidemic in man many years previously and have remained hidden and unchanged in some unknown place ever since. Evidence for this kind of event has been obtained. The strain of 'Russian 'flu' (H1N1) which reappeared in Anshan in northern China on 4 May 1977 and subsequently spread to the rest of the world, seems to be identical, in all genes, to the virus which caused an influenza epidemic in 1950^{27,28}. Where was this virus for 27 years? As yet we have no answer.

Second, some of the 'new' viruses may be derived from animal or avian viruses. One strain of human influenza has been shown to be such a recombinant (reassortant)²⁹⁻³¹. The Hong Kong (H3N2) virus contains the NA (and other) genes from an Asian (H2N2) strain of human influenza and a HA which is antigenically related to that of A/Duck/Ukraine/63 (H3N8) and A/equine/2/Miami/63 (H3N8) viruses^{24,25}. The amino acid sequence homology between the HAs of A/Duck/Ukraine/63 and A/Aichi/2/68 viruses (both of subtype H3) is 96%. We do not know if it was an animal or bird virus which donated the HA gene during the recombination event that led to the formation of the Hong Kong strain. The donating virus could have been one which contained Hong Kong HA that had persisted from a much earlier human influenza epidemic maintained unchanged in the same way as the Russian 'flu. Antibodies in the sera of people who were born around 1900 suggest that a virus with a HA similar to that of the Hong Kong virus caused influenza at that time³², but the NA of this virus was N8, not N2. It is possible that viruses such as equine (H3N8) and duck/Ukraine have evolved from the 1900 epidemic strain.

The third way in which new viruses could appear in the human population is if an animal or bird virus became infectious for man. This could be brought about by mutation, but the number of mutations required and the genes in which these would need to occur are unknown.

Perhaps each of these mechanisms has operated at one time or another to produce a 'major shift' in influenza viruses infecting man. We do not know how the different subtypes of type A influenza arose, but it is reasonable to suppose that 'shuffling' of genes between influenza A strains is occurring all the time, most frequently in birds³³, but also in mammals, including man^{34,35}.

Antigenic drift

Antigenic drift in the HA occurs by mutations in the gene, leading to an accumulation of amino acid sequence changes that alter the antigenic sites in such a way that they are no longer

recognized by the host's immune system. The evidence for this mechanism comes from sequence analysis of naturally occurring 'drifted' viruses (mainly those of the Hong Kong (H3N2) virus) and of variants selected in the laboratory in the presence of antibodies. Most of the sequence changes occurring in Hong Kong HA between 1968 and 1979 were in the HA1 portion of the HA molecule, only three changes being found in HA2¹⁷. The sequence changes in HA1 during this period are shown in chronological order of isolation of the strains in Fig. 3. Although these changes are distributed over HA1, on the three-dimensional structure of the HA many are clustered into four regions (Fig. 1) which are assumed to be the antigenic sites on the HA. Sequential changes at a particular position in HA1 have not occurred. A few apparent reversions were seen, but as there is no reason to believe that the viruses examined represent a direct genealogical lineage, it is likely that in those cases in Fig. 3 where there are apparent reversions of an amino acid, the real explanation is that the residue never changed in the first place. Similarly, in the one case where there is an apparent sequential change in an amino acid (the asparagine residue at position 137 changing to serine in Vic/75 and then to tyrosine in Bangkok/1/79), the nucleotide changes involved indicate that the Vic/75 strain was not the progenitor of the Bangkok/1/79 strain.

Some regions of HA1 have been totally conserved during the period 1968–79. The largest of these conserved regions occurs between residues 84–121 and 279–328. The latter block is also conserved in the two avian H3 strains so far sequenced^{24,25}, except for a single change of valine to isoleucine at position 309. Residues 279–328 form part of the 'stalk' of the HA where structural constraints may necessitate that they are highly conserved.

Variants selected with monoclonal antibodies

Antigenic variants of the HA have been selected by growing virus in the presence of monoclonal antibody to the HA. The variants occurred at a frequency of $\sim 10^{-5}$ in virus stock^{36,37} and did not bind at all to the antibody used for their selection. This dramatic change in antigenicity was found to be associated with single changes in the amino acid sequence of HA1^{15,37} (see Fig. 3). Most antigenic variants of Mem/1/71 (H3N2) selected with monoclonal antibodies could not be distinguished from parental virus with antisera from ferrets infected with the parent strain, but two could be distinguished¹³. Some antigenic variants of B/Hong Kong/1/73 could also be discriminated³⁸. Presumably, their amino acid substitutions (Fig. 3) cause more profound changes in the antigenicity of the molecule than others. It seems likely that only variants which have such profound changes have sufficient selective survival advantages in an immune population to produce an epidemiological impact.

Variation in neuraminidase

Neuraminidase is an integral membrane protein in influenza virus and can be solubilized with detergents or pronase³⁹. The detergent-soluble NA has a molecular weight^{40,41} of ~240,000 and consists of four identical polypeptide chains arranged in such a way that the molecule possesses a hydrophilic 'head' attached to the hydrophobic membrane-insertion sequence by a thin stalk. The active centre of the enzyme and the antigenic determinants are distinguishable from each other⁴². Pronase digestion of the virus releases the soluble NA head of M_r ~200,000 which retains the antigenic and enzymatic activity of the intact molecule. The NA heads of some strains of influenza virus can be crystallized⁴³ and determination of the three-dimensional structure of A/Tok/3/67 (H2N2) NA is in progress⁴⁴. The Fab fragment from a monoclonal antibody to A/Tok/3/67 (H2N2) NA has also recently been crystallized and the complementary surfaces of this antigen-antibody complex can now be mapped⁴⁵.

The complete sequence of the NA gene of A/PR/8/34 has been determined⁴¹ and from the predicted amino acid sequence and analysis of intact NA and NA heads of N2, N5 and N8

Table 1 Influenza virus-coded proteins

	Approximate no. of molecules		Molecular w	eight estimated by			
Designation	per virus particle	Gel electrophoresis	Gene sequence*	Gene + protein sequence	Ref.	Remarks	
P1 polymerase 1 P2 polymerase 2 P3 polymerase 3 HA haemagglutinin	} 30–60	96,000 87,000 85,000			91 91 91	Internal proteins associated with RNA transcriptase activity.	
HA1				36,074+11,500 (Mem/102/72)†	22,84	Surface glycoprotein responsible for attach- ment of virus to cells.	
H A 2				27,368+1,400 (Mem/102/72)†	23,84	Trimer composed of two polypeptides HA1 and HA2 formed by post-translational cleavage of the primary translation product. Three-dimensional structure known.	
NP nucleoprotein	1,000	50-60,000	56,106		55	Internal protein associated with RNA and polymerase proteins, helical arrangement.	
NA neuramınıdaşe	100	48–63,000	50,087		41	Surface glycoprotein, with enzyme activity. Tetragonal molecule with a 200,000-M _r , head—crystallized and structure in progress.	
M1 matrix	3,000			27,861	58, 59, 62	Major virion component surrounding the core, involved in assembly and budding.	
M2 matrix		15,000	11,000		10	Coded from the same gene segment as M1 in a second reading frame, a non-structural protein, function unknown	
NS1 non-structural protein		25,000	26,815		64	Non-structural protein, function unknown.	
NS2 non-structural protein	ı	12,000	14,216		64	Non-structural protein coded for in a second reading frame from same gene segment as NS1, function unknown, synthesized late in infection	

^{*} These values are from the predicted amino acid sequence and do not take into account any processing the final product may have undergone

subtypes^{7,46} it has been found that, unlike the HA, the NA is oriented with its N terminus buried in the viral membrane and does not have a signal peptide which is cleaved.

Antigenic shift and antigenic drift occur in the NA; among the human influenza viruses antigenic shift occurred in 1957, with the emergence of the H2N2 subtype and the replacement of the N1 by N2. Antigenic drift in the NA of influenza viruses⁴⁷⁻⁴⁹ has been correlated with differences in amino acid sequences^{43,50}.

Partial sequences up to 340 nucleotides from the 3' end of the NA gene have been obtained for representative viruses from eight of the nine NA subtypes⁵¹. These sequences will correspond to the region encoding the N-terminal part of the NA since analysis of tryptic peptides shows that translation begins from the first AUG codon and that no signal peptide is cleaved from the N terminus. The first six amino acids are conserved in all viruses of all subtypes examined and the next six are conserved in most subtypes. Following these, the nucleotide and predicted amino acid sequences of the eight subtypes of NA differ dramatically in the hydrophobic membrane insertion sequence and the extended structure of the stalk. Deletions and/or insertions of short blocks of nucleotides in the NA gene are seen within subtypes⁵².

Antigenic variants of the NA have been selected using monoclonal antibodies at a frequency of ~ 1 in 10^5 (ref. 53), similar to the frequency of variants in the HA molecule³⁶. Analysis of antigenic variants with a panel of N2 monoclonal antibodies provided evidence for at least three and possibly four non-overlapping antigenic areas on the NA molecule of A/Tokyo/3/67⁵³. Studies on natural antigenic drift indicate that it occurs by the same mechanisms as in the HA, with a limited number of base changes in the NA gene within subtypes⁵⁴.

Variation in the nucleoprotein

The nucleoprotein (NP) is one of the group-specific antigens of influenza viruses that distinguishes between the influenza A, B and C viruses. It probably constitutes the backbone of the helical internal complex that is associated with the RNA segments and the three different polymerases.

The NP gene of A/PR/8/34 virus is 1,565 nucleotides long and is capable of encoding a protein of 498 amino acid residues

(M_r56,106) rich in arginine⁵⁵. Double immunodiffusion tests showed antigenic differences between the NPs of H1N1 and the H3N2 strains⁵⁶ and recent studies with monoclonal antibodies to the NP of A/WSN/33 (H1N1) viruses have shown that antigenic variation occurs in this molecule⁵⁷. The NP molecule possesses at least three non-overlapping antigenic areas, one area being the same on all strains tested. Monoclonal antibodies to this conserved domain inhibited *in vitro* transcription of viral RNA, suggesting that this region of the NP is involved in RNA transcription⁵⁷.

The matrix protein

The complete sequence of RNA segment 7 (M) of two strains of A/PR8/34 (H1N1)^{58,59} and of A/Udorn/72 (H3N2)⁶⁰ has been reported as well as partial sequences of a number of strains⁶¹. Following the first AUG codon in the positive strand, a 252-residue protein, rather hydrophobic and rich in arginine, is encoded. Compositions of tryptic peptides from purified matrix protein of PR8⁶¹ correspond well with those expected from the amino acid sequence predicted from the gene sequence.

Comparison of the sequences of RNA segment 7 of the H3N2 (Udorn) and H1N1 (PR8) strains shows that the sequences coding for the matrix (M) of these viruses isolated 38 years apart are highly conserved⁶⁰, in keeping with antigenic studies⁶². Comparison of 230 nucleotides of RNA segment 7 from five human H1N1, H2N2 and H3N2 strains isolated over a 43-yr period suggests that the same segment 7 was retained throughout the antigenic shifts of HA and NA type (H1N1 to H2N2 to N3N2)⁶¹. In addition, the complete sequences contain a second open reading frame which overlaps the M protein sequence by 68 nucleotides.

Three mRNAs transcribed from RNA segment 7 have been isolated. One (M1 mRNA) consists of an uninterrupted, nearly full-length, copy of RNA segment 7 and is responsible for the production of the M protein. An M2 protein is generated from a spliced product of the M1 mRNA, such that after the nucleotides encoding the N-terminal nine amino acids, nearly 600 nucleotides are spliced out and the reading frame is changed; a protein product corresponding to this has been identified in infected cells¹⁰. In addition, a third mRNA has been found, which would code only for a 8-residue peptide identical to the C terminus of M1⁶³. Such a product has not yet been isolated.

[†] The second value is the carbohydrate contribution.

The non-structural proteins

Recent studies have shown that RNA segment 8 codes for at least two non-structural polypeptides, NS1 and NS2, which are translated from separate mRNAs⁶⁴⁻⁶⁶. Mapping and sequence studies have shown that NS1 and NS2 overlap by 70 amino acids that are translated from different reading frames. Polypeptides NS1 and NS2 share 9 amino acids at their N termini, but after this sequence the mRNA for NS2 has a deletion of 423 nucleotides, then rejoins the rest of the mRNA in the +1 reading frame. The function of NS1 or NS2 has not been established. NS1 is made in large amounts and accumulates in the nucleus⁶⁷; NS2 is made late in infection and is found predominantly in the cytoplasm^{64,68}.

Because NS1 and NS2 are internal proteins of infected cells and hence less available to antibodies, they would be expected to show less sequence variation than the surface glycoproteins (HA and NA). Accordingly, comparison of the sequences of the NS genes of fowl plague⁶⁵ and the two human influenza strains A/Udorn/72 (H3N2) and A/PR/8/34 shows only 8-11% differences^{64,69,70}. An open reading frame potentially coding for a polypeptide has been noted in the noncoding, virion RNA of the NS genes of A/PR/8/34, Udorn/72 and FPV, but is not present in the NS gene of duck/Alberta/60/76⁷¹. No protein corresponding to this extra 'gene' has yet been identified.

Polymerase proteins

The three largest proteins of the virion (P1, P2, P3) with M,s of 96,000, 87,000 and 85,000, respectively, are found in association with the nucleoprotein and virion RNA and carry the polymerase activity⁷² which transcribes the invading viral RNA⁷³. Proteins P1 and P3 are probably required for complementary RNA synthesis and P2 and NP for virion RNA synthesis⁷⁴.

Transcription of the viral RNA segments soon after infection terminates ~40 nucleotides before the 5' end to give messenger RNAs⁷⁵; these mRNAs have a cap structure and a heterogeneous sequence of 10–13 nucleotides derived from cellular mRNAs at their 5' end⁷⁶. Later transcripts are full length and act as templates for synthesis of the genes of the progeny virus. The complete nucleotide sequences of two of the three polymerase genes of the A/PR/8/34 strain have been determined⁷⁷, but the extent of variation in the polymerase genes is unknown, although these may play an important part in host range and virulence.

Defective interfering (DI) influenza virus particles are generated by high multiplicity passage in permissive cells. These particles are of interest because they facilitate the establishment of persistent infection in cell cultures and could therefore be concerned in latency. They contain new small RNA molecules which are absent from infectious virus and which are generated predominantly by massive internal deletion from the three P genes^{78,79}, although the sequences of one small RNA is a mosaic of several segments from at least two of the polymerase genes^{77,80}. This is the first time intragenic recombination has been shown in influenza virus.

Variation in pathogenicity

Highly pathogenic avian influenza viruses that cause generalized infections and death in avian species exist among viruses of the H7 (formerly Havl) and H5 (Hav5) HA subtypes, while other viruses of these subtypes are relatively non-pathogenic although fully infectious. Efficient cleavage of the precursor HA polypeptide into HA1 and HA2 in a wide range of cells from different tissues appears to be essential for the pathogenicity of these viruses⁸¹⁻⁸³. The amino acid sequence of the connecting peptide between HA1 and HA2 may determine the range of cells in which cleavage can occur. Fowl plague virus, which produces almost invariably lethal infections in chickens, has the sequence Lys-Lys-Arg-Gln-Lys-Arg between the C terminus of HA1 and the N terminus of HA2¹⁸, while the human viruses, which are avirulent in chickens, and non-pathogenic avian viruses of the same subtype as fowl plague (H7), contain only a

single connecting arginine residue ^{6.17,22,23,84}. Investigation of groups of pathogenic and non-pathogenic avian influenza viruses of the H7 subtype suggested that the HA molecules from the non-pathogenic viruses had fewer basic residues in their connecting HA peptides than the pathogenic strains⁸⁵.

Examination of the amino acids of the amino-terminal sequence of HA2 of several influenza A viruses of human and avian origin has revealed a highly conserved region of 10 residues ^{86,87}. This sequence is homologous ⁸⁸ to the amino-terminus region of the fusion glycoprotein F, of Sendai virus (a paramyxovirus), which mediates fusion of the Sendai virus envelope with the plasma membrane of host cells, a function which is considered essential for virus infectivity. It has been postulated, therefore, that the infectivity of influenza virus is dependent on a fusion function of HA analogous to that of the Sendai fusion protein. Although the three-dimensional structure of the influenza HA shows that this peptide is buried in the molecule, it has recently been shown that after incubation in conditions required for membrane fusion, that is, at pH 5.0, a conformational change occurs in the influenza HA glycoprotein and the molecule acquires the ability to bind to lipid vesicles ⁸⁹.

However, the structure of the HA is almost certainly not the only factor determining pathogenicity. While reassortment studies between highly virulent and avirulent viruses pointed to the prime importance of the HA for pathogenicity, they also showed that the polymerase (P3) and nucleoprotein genes could be involved. Other experiments have shown that a specific gene constellation, rather than any single gene, is responsible for the pathogenic properties.

What of the future?

The recent explosion of structural data on the genes and gene products of influenza viruses has provided some important information about the behaviour of this virus. For example, it is clear that antigenic shift does not occur by direct mutation of one subtype into another, while antigenic drift occurs by point mutation in the genes. However, the mutation frequency of the surface proteins is not significantly greater than that of the internal proteins. HA possesses at least four distinct antigenic sites which can vary independently, with pathogenicity depending in part on the sequence in the HA where cleavage occurs. Some RNA segments of the virus possess overlapping genes, using two reading frames. The sequence data support the antigenic classification of the HA and NA subtypes.

However, many mysteries remain. Shifts can occur by the emergence of viruses which previously caused epidemics and have remained unchanged, as if frozen, for many years. Where these viruses hide, and what causes them to re-emerge, is a complete mystery. The shifts may also occur by genetic reassortment of human and animal influenza viruses or by mutation of an animal or avian virus so that it becomes able to infect people. Most type A influenza virus subtypes are found in birds, but the role of these in the emergence (or re-emergence) of new subtypes in man is not clear; nor is it clear why the shifts always occur in China or why the old subtypes usually disappear from man as the pandemic of new virus starts. On the other hand, the Hong Kong subtype did not disappear when Russian 'flu started and we do not know why this was.

What is the origin of the various subtypes? How many subtypes are there in birds and animals as well as in man? Can all subtypes of HA and NA be incorporated into viruses infecting man? Why are the antigenic shifts restricted to type A influenza? What triggers the appearance of a new subtype?

It is not known precisely how the amino acid sequence changes which occur in the HA and NA during drift alter the antigenic properties. Does drift follow a set path and can drift be predicted? Why do few, if any, sequential changes at particular positions in the HA molecule occur?

Are there particular areas on the HA and NA which induce neutralizing antibody while others do not? Does drift involve changes in the immunogenicity of different antigenic determinants? The location on the HA molecule of the sequence changes which occur during antigenic variation in the H3 subtype is known, but whether the amino acids in these areas make contact with the combining site on antibody molecules is not.

Does drift continue indefinitely? Can it go backwards? It is not known if the same antigenic change occurs simultaneously in different areas of the world or whether a single mutant arises somewhere and all spread derives from a single focus. Why does antigenic drift occur in influenza, but not, for example, in paramyxoviruses such as measles virus, where antigenic variants can be selected *in vitro* with monoclonal antibodies at about the same frequency as influenza^{92,93}?

Why does one sometimes observe 'original antigenic sin', in which a virus may preferentially elicit antibodies against a previous strain which has since disappeared? In addition to antigenic variation, variation in host range, virulence and transmissibility greatly influence the severity of the disease and the spread of epidemics. Is it possible that a virus could appear which would cause the same degree of mortality as the 1918 'swine' 'flu epidemic? What influences the spread of influenza virus, and why do epidemics normally appear in the winter, thus oscillating between the Northern and Southern Hemispheres? It is not known why epidemics are self-limiting, even when susceptible hosts remain in abundance.

There are now, however, better prospects for the control of influenza. Effective and safe live vaccines may be made in the future using modern genetic engineering techniques. Synthetic vaccines may be possible where the antigens are pure enough for the vaccines to be given in large enough doses to be effective and engineered such that they do not induce original antigenic sin. A universal vaccine, which protects against all members of a

subtype or even across subtypes might be feasible. It might also be more rewarding to look for ways of increasing the cellular immune response as well as the humoral response.

With the three-dimensional structure of at least one HA

With the three-dimensional structure of at least one HA molecule known and candidates for the antigen and receptor binding sites tentatively identified, the way is open for the synthesis of vaccines containing key segments of HA molecules. HA antigenic determinants can be detected in *Escherichia coli* transformed with a plasmid carrying a cloned HA gene^{94–96}, and copious amounts of HA appear on the surfaces of eukaryotic cells infected with a simian virus 40 (SV40) vector containing the HA gene^{97,98}. These experiments open the way to the use of site-directed mutagenesis to tailor the HA into a successful synthetic and possibly universal vaccine.

What of the immediate future? We do not know if another antigenic shift is imminent. If a new virus does suddenly appear, will the structural data tell us where it came from? The new virus might not have the capacity to kill people in the same way as the recent seal virus killed seals, but if it did, it is doubtful that we would be able to stop it causing world-wide devastation. If no shift occurs, what will happen to the currently circulating H3N2 and H1N1 strains? Will they continue to drift, or have they reached their limit? There is little doubt that a greater understanding of the molecular biology and genetics of the virus will make an essential contribution in piecing together the answers to the puzzle of influenza.

Revisions of K/Ar ages for the Hadar hominid site, Ethiopia

Robert C. Walter* & James L. Aronson

Department of Geological Sciences, Case Western Reserve University, Cleveland, Ohio 44106, USA

Conventional K/Ar age measurements are reported for two volcanic units from the hominid-bearing Hadar Formation. These ages represent revision of previously published ages for the BKT-2 tephra and the Kadada Moumou basalt. BKT-2 is revised from 2.65 to 2.9 Myr BP and the Kadada Moumou basalt is revised from 3.0 to 3.6 Myr BP.

PREVIOUS isotopic age determinations for the Hadar Formation relied on two volcanic horizons, the BKT-2 tephra in the upper Kada Hadar (KH) Member and the Kadada Moumou basalt (KMB) in the upper Sidi Hakoma (SH) Member (Fig. 1). New work has focused on additional dating of these two units as well as on many of the other tuffs in the formation that are less adequate for dating¹. This article presents revised geochronology for the BKT-2 tuff and of the Kadada Moumou basalt. The revisions are based on three components: (1) new abundance and decay constants for ⁴⁰K that are now widely accepted²; (2) new values for the ³⁸Ar internal standard used in the study; and (3) running of additional samples that have shed new light on the age interpretation. These considerations cause us to propose an increased age for these units.

New decay and abundance constants for 40K

In August 1977, the International Union of Geological Sciences (IUGS) Subcommission on Geochronology proposed a revision of the decay constants and the atomic abundance of 40 K (ref. 2). The new constants are $\lambda_{\star}=0.581\times10^{-10}~\text{yr}^{-1},~\lambda_{\beta}=4.962\times10^{-10}~\text{yr}^{-1},~\text{and}~^{40}\text{K/K}=1.167\times10^{-4}.$ Plio–Pleistocene K/Ar ages calculated with the old constants are increased by $\sim\!2.7\%$ when recalculated with the new constants³. Therefore, previously published K/Ar ages for the Pliocene Hadar Formation $^{4-6}$ must be categorically increased by 2.7%.

Revision of CWRU ³⁸Ar pipette constants

The K/Ar laboratory at Case Western Reserve University (CWRU) utilizes a bulb $^{38}{\rm Ar}$ tracer system with an all-metal, two-valve gas pipette machined in Heidelberg after the type used at the Max Planck Institute. The bulb was filled with the $^{38}{\rm Ar}$ residue remaining after a commercial preparation of $^{38}{\rm Ar}$ batch tracers. A discrepancy arose between the pipette volume calculated from the amount of $^{38}{\rm Ar}$ stipulated for the initial fill by the commercial glassblower and the pipette volume measured by the machinist who made the pipette. In our previous reports on the Hadar Formation $^{4-6}$ the 'calculated' rather than the 'measured' volume was used and we reported an average of $18.4\times10^{-10}\,{\rm mol}\,{\rm g}^{-1}$ of $^{40}{\rm Ar}^*$ (radiogenic argon) for the LP6 interlaboratory biotite standard. This value is significantly lower than the accepted LP6 $^{40}{\rm Ar}^*$ yield of $19.3\times10^{-10}\,{\rm mol}\,{\rm g}^{-1}$ (J. C. Engles, personal communication).

We have now pipetted over 1,000 aliquots from the bulb system and monitored its depletion against 35 analyses of the LP6 standard (Table 1). The depletion behaviour (Fig. 2) is only explained by the machinist's measurement of the pipette volume (method B) and not by the glassblower's calculation of the initial $^{38}\mathrm{Ar}$ content (method A). Thus we have recalibrated our $^{38}\mathrm{Ar}$ internal standard to the measured pipette volume and recalculated the initial $^{38}\mathrm{Ar}$ fill to correspond to the accepted value of 19.3×10^{-10} mol g $^{-1}$ of $^{40}\mathrm{Ar}^*$ for the LP6 biotite standard.

Table 1 shows our results for several inter-laboratory standards including LP6 biotite, MMhb hornblende (University of Minnesota), SB biotite (US Geological Survey), Bern 4M muscovite and Bern 4B biotite and Berkeley African Feldspar: (BAFIS) A, B and C (ref. 7 and personal communications from J. C. Engles, M. Lanphere, and E. Jager).

In Tables 2 and 5 all previously published K/Ar ages for the Hadar Formation have been corrected for the recalibrated ³⁸Ar pipette constant as well as the new radiometric and abundance constants.

Additional samples and new measurements

BKT-2, believed to be a primary ash-fall tuff, overlies nearly all of the fossil vertebrate fauna of the Hadar Formation⁵ (Fig. 1). The tuff commonly occurs as a doublet horizon, with the upper ash layer (BKT-2u) separated from the lower ash layer (BKT-2L) by 0.5-1.0 m of fluvial overbank silty clay⁸.

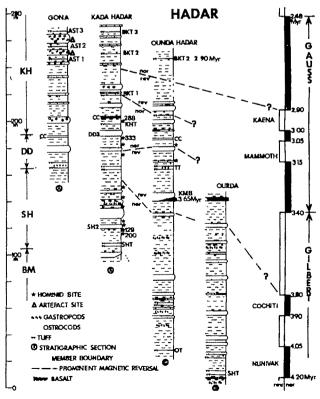

Fig. 1 Stratigraphical sections proceeding from west (left) to east (right) across the Hadar Site (taken from ref. 8) Location of sections shown in Fig 3. Prominent magnetic polarity reversals and their possible correlation to the worldwide reversal time scale (ref. 3) are indicated.

Personal communications from †J C Engles, ‡M. Lanphere, § E. Jager.

Two samples of BKT-2u were collected independently, from the Bouroukie wadi, a tributary to the Kada Hadar drainage (Fig. 3). Each sample was gently wet-disaggregated to preserve the original grain sizes. The samples were washed for 10 min in dilute (\sim 4%) HF, and sonified to rid the minerals of adhering clay particles, thoroughly rinsed with de-ionized H₂O and air dried. They were subjected to density, sieving, and magnetic separations.

BKT-2u contains a simple, euhedral, volcanic phenocryst assemblage consisting of 25% anorthoclase, 1% aegerine-augite, and common magnetite octahedra and zircon. The phenocrysts are encased in a matrix of collapsed pumice clasts. Small, 0.05–0.10 mm, magnetite octahedra and zircon crystals are common inclusions in the larger, 0.50–1.50 mm anorthoclase and aegerine-augite phenocrysts⁵. In addition, BKT-2u contains 0.5–2.0 mm, angular fragments of vesicular basaltic glass previously misidentified as obsidian, and basaltic rock fragments, perhaps incorporated during a mixed magma eruption¹. Anorthoclase and zircon were used for K/Ar and fission track dating, respectively^{1,4–6}.

One of the collected BKT-2u samples, sample 1, was subjected to a very refined size, density and magnetic separation to isolate anorthoclase of different physical properties that could be tested for K/Ar age concordance.

The first K/Ar age reported for BKT-2u was 2.63 ± 0.05 Myr BP (ref. 5), which is the mean and 1σ standard deviation of four measurements of the same light, non-magnetic, 35/80 mesh anorthoclase fraction from sample 1(tracers 277, 279, 297, and 311; Table 2). Additional measurements were reported on two finer size fractions of sample 1 anorthoclase (tracers 470 and 471; Table 2) and on a dense, magnetic separate in which each anorthoclase crystal contains a small (\sim 0.5 mm) octahedral magnetite inclusion (tracer 472; Table 2). We also report two new K/Ar measurements made on the second BKT-2u sample, sample 2 (tracers 874 and 876; Table 2) and three measurements for a 35/80 mesh anorthoclase fraction separated from BKT-2L (tracers 466, 467 and 468; Table 2). Note that sample 2, BKT-2u, was not subjected to such a refined density and magnetic separation as sample 1.

In all, 14 conventional K/Ar measurements have been made on BKT-2. These are listed in Table 2, corrected for new decay, abundance and tracer constants. The 14 age determinations yield a mean age and standard deviation of the measurements of 2.93 ± 0.11 Myr BP with an absolute range 2.75-3.12 Myr.

Note, however, that the K/Ar measurements of sample 2, BKT-2u, yield a slightly older set of ages, from 3.02 to 3.12 Myr. This compares with the range of sample 1 measurements from 2.75 to 2.98 Myr. The mean and standard deviation for sample 2 and sample 1 are 3.07 ± 0.05 and 2.88 ± 0.08 Myr BP, respectively. Zircon fission track data show that BKT-2u contains two zircon age populations; a dominant one around 2.7 Myr BP and a minor component around 5.0 Myr BP (ref. 1). This suggests that the older K/Ar measurements on sample 2 could be due to trace amounts of possible contaminating feldspars associated with the older zircon component. The younger set of K/Ar ages

measured for sample 1 could be due to the exclusion of detrital feldspars because of the more refined laboratory separation process that sample 1 underwent. However, even sample 1 feldspars may have suffered some contamination.

The concordance of all K/Ar measurements for various fractions of sample 1 argues that any contaminating effect is minimal. The concordant age group, 2.88 ± 0.08 Myr BP, includes measurement of the magnetic anorthoclase fraction in which every feldspar grain contains an octahedral magnetite inclusion. We feel that this inclusion trait fingerprints the BKT-2 U and L eruptions, and is too rare for the tephra to contain contaminants of similar grains from an older eruption. Finally, we stress that the lever arm exerted on the measured age by detrital contamination is much less at Hadar than at most East African sites. This is because the sediments at Hadar are dominantly volcaniclastic with measured K/Ar and fission track ages on the detrital components being less than 30 Myr (ref. 6).

We accept the 2.88 ± 0.08 Myr BP mean age as the most precise K/Ar measurement of the BKT-2 eruption. The fission track age of the dominant younger component of BKT-2u is 2.7 ± 0.2 Myr BP (ref. 1), which is within the uncertainty of the K/Ar age but further work is needed to improve its precision.

Kadada Moumou basalt

The Kadada Moumou basalt (KMB) crops out along the Ounda Hadar wadi (Fig. 3), in the upper part of the Sidi Hakoma (SH) Member of the Hadar Formation (Fig. 1). The correlation of KMB with the fossil hominid localities in the lower SH Member, such as A.L. 200, is not precisely established. The SH Member

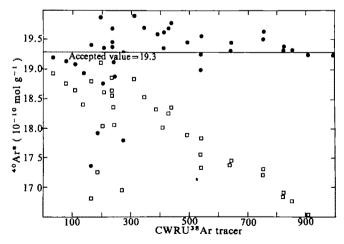

Fig. 2 Monitoring the depletion of the CWRU (Case Western Reserve University) ³⁸Ar tracer bulb against the LP6 biotite interlaboratory standard. Method A (□) utilizes glassblower-stipulated ³⁸Ar in the initial fill and an 18.6×10⁻¹⁰ mol g⁻¹ of ⁴⁰Ar* value for LP6. Method B (●) uses the machinist stipulation of the pipette volume and 19.3×10⁻¹⁰ mol g⁻¹ of ⁴⁰Ar* for LP6. Method A is wrong, method B is correct.

thickens from ~70 m at Kada Hadar, where no basalt occurs but where numerous hominid localities exist, to ~160 m at Ounda Hadar and Ourda, where the basalt crops out, but where no hominids are found (Figs 1 and 3). KMB is probably stratigraphically above the lower SH Member hominid finds, as judged by (1) proportioning the stratigraphical thicknesses between the Kada Hadar and Ounda Hadar-Ourda sections: (2) by tentative correlation of gastropod-bearing layers above most of the hominid levels with similar layers below the basalt; and (3) by correlation of a prominent palaeomagnetic polarity transition, from normal to reverse, that occurs below the basalt in the Ounda Hadar section and above the gastropod layers in both the Ounda Hadar and Kada Hadar sections (Fig. 1)5. The KMB is, however, stratigraphically below such important hominid localities as A.L. 333 and A.L. 288 in the Denen Dora (DD) and Kada Hadar (KH) Members, respectively, because the KMB is definitely below the Triple Tuff (TT) and Ostracod clay marker horizons which form the base of the DD Member (Fig. 1).

Initial chronological measurements for the Hadar Formation centred around the KMB^{4,5}. This lava is a moderately low

potassium (~0.6% K₂O) tholeiite, which displays various stages of alteration depending on position in the 2-3 m thick flow. The base of the flow is conformable with sediments of the Hadar Formation. The sediments were baked to a depth of 2-3 cm, and the base of the flow was supercooled forming a 2-3 cm thick chilled zone. Protruding upwards from this contact are abundant bent 15-cm long calcite-filled pipe vesicles. These contact features suggest that the lava erupted over very shallow water or over water saturated sediments. The sedimentary environment over which the lava flowed is interpreted as a floodplain or marsh⁸. The reaction between lava and water-saturated sediments probably caused severe hydration of the lava¹.

Type A and B Kadada Moumou basalts

Recovery and dating of a new, unique basalt sample from the Kadada Moumou flow is a major factor which caused us to revise our minimum age estimate of 3.0 ± 0.2 (refs 4, 5) to $3.60\pm$ 0.15 Myr (ref. 1). The unique variety of this flow is termed 'type B'; all previously published data for KMB were accomplished on 'type A' varieties. These two varieties can be distinguished petrographically as well as geochronologically.

In general, the KMB is not ideal for dating because of variable alteration of the basaltic glass and mesostasis to a nontronite clay. The alteration presumably developed diagenetically after initial hydration of the flow, as described above. Being aware of the variable amount of clay alteration in KMB⁵, we conducted a detailed search of the flow and recovered a uniquely leastaltered sample, KM76-5. This sample was collected in situ from the core of an oblate, spherical structure about 20 cm in diameter, within the middle of the 3-m thick flow. The core of the sample consists of dense, fine-grained basalt that grades radially outward to a zone containing minor flattened, nontronite-filled amygdules. The rim of the structure contains abundant, flattened, and rounded nontronite-lined and filled vesicles. This structure conceivably originated as a cooled block of the lava flow reincorporated into the flow. Its major and trace element chemistry is identical to the rest of the flow (Table 3). The petrography of type B KM76-5 is, however, unique in that it is more nearly holocrystalline (Table 4) and essentially all of its glass is unaltered. In addition, the plagioclase and pyroxene of the type B variety are finer grained than type A varieties (Table 4) and the magnetite is equant (cubic) rather than rod-shaped

[†] Data corrected for new ³⁸Ar depletion constant ‡ Data corrected for new ⁴⁰K decay and abundance constants.

[§] Each grain contains a magnetite octahedron

^{*} X-ray fluorescence

(acicular). Type A samples contain significantly greater amounts of glass, altered glass, and nontronite than type B samples, and their crystals are much coarser grained (Table 4).

Initially, a random piece of KM76-5 was prepared for K/Ar analysis. Subsequently, two additional samples were obtained by sectioning the core of the boulder into thin slabs. The sample was then sawn into two fractions, one labelled F (fair), which contained minor nontronite-filled vesicles, and the other labelled G (good), which was less vesicular. The nontronite in the type B basalt is thought to be a secondary amygdale fill and not an alteration product of the basaltic glass because, in thin section, the nontronite can be seen to be relegated to vesicles, and virtually none of the matrix is altered.

K/Ar data

The resultant mean and standard deviation of eight measurements of the KM76-5F sub-sample is 3.64 ± 0.12 Myr BP. For five measurements of the KM76-5G sub-sample this is 3.54 ± 0.12 Myr BP. Three runs of the original bulk sample, KM76-5, yield a mean value of 3.67 ± 0.10 Myr BP. Thus, the 16 measurements of the three sub-samples of the type B variety are internally concordant with a mean age of 3.61 ± 0.13 Myr BP.

In addition, type B samples produced uniformly higher proportions of radiogenic argon, ~25%, compared with only

~15% radiogenic argon for type A samples (Table 5). This enhancement of radiogenic argon is mainly due to a reduction in contaminating atmospheric argon, the additional radiogenic argon being a minor component. Typically, we and others observe the general correlation that the per cent radiogenic argon yield is inversely proportional to the amount of secondary alteration 1,10-12. We interpret the lack of alteration of the type B sample as due to the dense core structure preventing access of altering solutions.

In contrast to the type B variety of the flow, the type A basalts produce uniformly lower measured ages (Table 5, revised for new constants and tracer factor) with some ages as young as 3.0 Myr (revised; petrographical type A-1) and others higher at 3.3 Myr (revised; type A-2). K₂O and Ar measurements on physical separates of the sugary-textured2 type A-1 basalt were attempted to see if a single sample could be shown to be internally discordant between low density glass-rich, nontronite-rich fractions and heavy glass-poor, nontronite-poor fractions. Initially, a rough separate into two density fractions was performed on type A-1 sample KM-2-74 (lab) and the heavier fraction was analysed (sample 1, Table 6). A large separate piece (sample 2) was then disk pulverized and subjected to a careful size/density separation into eight fractions (sample 2, Table 6). Modal counts were made on grain mount

thin sections (Table 4) and 6 fractions were analysed for K_2O and Ar (Table 6).

The heavier fractions, being poor in glass and nontronite and rich in pyroxene (Table 4), are considerably lower in K_2O (0.4–0.5% K_2O). The light fractions are rich in glass, nontronite, and plagioclase (Table 4) and high in K_2O (1.07–1.12% K_2O ; Table 6). The heaviest fractions (sink 1) produce uniformly older ages, with four measurements having an average and standard deviation of 3.5 ± 0.5 Myr. For this separation experiment most of the separates were not pre-baked and yielded a low percen-

tage of radiogenic argon that resulted in a large internal imprecision in the individual argon measurements.

These results, though imprecise, indicate that the altered type A basalt is internally discordant. The data associate younger ages with more abundant glass, a phase that is prone to argon loss, or with more nontronite that is, in part, observed to be an alteration product of glass in type A basalts.

The possibility that the type B Kadada Moumou basalt has some excess magmatic ⁴⁰Ar has to be considered. We think this is unlikely, however, because of the rarity of examples of excess

argon in aphanitic terrestrial basalts¹⁵. The flow is extensive and thin enough that it should have thoroughly degassed. Furthermore, there is no evidence for older acidic crust in western Afar¹ that could have contaminated the magmas as was indicated for the New Zealand basalts studied by McDougall et al. 13; no xenoliths of cognate inclusions have ever been found in either the Kadada Moumou flow or numerous other western Afar flows¹. It is also unlikely that the flow picked up boulders or fragments of older basalt because the flow erupted onto overbank sediments of clay and clay-sized particles. On the contrary, there is a distinct inverse correlation of whole rock measured ages with degree of observed sample alteration and, in the type A fractionation experiment, with glass and nontronite content (Tables 4-6). Alteration typically causes ⁴⁰Ar loss (and K gain) in K/Ar systems. Therefore, we regard the spectrum of ages obtained from the Kadada Moumou flow as being due to alteration variably affecting the K/Ar age measurement. We regard the 3.60 ± 0.15 Myr BP age measurement of the type B basalt, the least altered variety of the flow, as a best-estimate minimum age for the flow. However, even the type B age requires some qualification because of the small, but perhaps significant, amount of alteration also seen in this variety.

Accepting the older 3.60 Myr age for the Kadada Moumou basalt necessitates a revised correlation of the Hadar palaeomagnetic sequence to the palaeomagnetic time scale: the details will be considered elsewhere. The Kadada Moumou flow and

overlying and underlying sediment are reversed. The revised age places the reverse sequence within the Gilbert Epoch which ended 3.4 Myr BP instead of in the Mammouth Event 3.15-3.05 Myr BP as previously interpreted (Fig. 1).

Conclusion

Adoption of new decay and abundance constants, recalibration of the ³⁸Ar laboratory tracer pipette and data from several new samples requires us to revise the K/Ar ages for the BKT-2 tephra, from 2.65 to 2.9 Myr BP, and the Kadada Moumou basalt, from 3.0 to 3.6 Myr BP. All the fossil hominid remains at Hadar are found below BKT-2, and many hominid localities occur stratigraphically below the Kadada Moumou basalt. Therefore, on the basis of this revised chronology, the fossil hominid material in the Hadar Formation is interpreted to range from at least 2.9 Myr BP to somewhat older than 3.6 Myr BP. These revised ages permit a correlation of the pre-basalt Sidi Hakoma Member hominid fossils at Hadar with the footprints and fossils at Laetoli which is 700 km to the south and well dated between 3.6 and 3.75 Myr BP (new constants)¹⁶

Initiation of ice ages by creep instability and surging of the East Antarctic ice sheet

Gerald Schubert* & David A. Yuen[†]

* Department of Earth and Space Sciences, University of California, Los Angeles, California 90024, USA † Department of Geology, Arizona State University, Tempe, Arizona 85287, USA

Creep or shear heating instability is shown to be a plausible means of initiating a surge of the East Antarctic ice sheet and plunging the Earth into an ice age. The occurrence of this instability requires only that the ice thickness exceed a critical value which may not be much larger than the present ice dome thickness. Creep instability can occur on the fast time scale of 100-1,000 yr required by inferences of past rapid cooling events and sudden rises of sea level before the onset of Northern Hemisphere glaciations.

THE Antarctic surge theory for the inception of ice ages invokes an instability in the ice sheet to melt its base and cause it to slide into the ocean, thereby forming a huge ice shelf around the southern continent. This would increase the Earth's albedo and lead to global climatic cooling and the inception of glaciation in the Northern Hemisphere. It would also produce a rapid rise in sea level by as much as 15-20 m at the end of an interglacial². Several lines of evidence indicate that these events did indeed occur near the end of the last interglacial3-6; in particular, the association of the >8 m sea level rise ~120,000 yr ago inferred from raised coral reefs in New Guinea with the 2 °C cooling of the surrounding ocean on a 1,000 yr time scale deduced from oxygen isotope studies of giant clam shells strongly supports the surge theory6. The magnitude of the sea level rise requires the surge of a large fraction of the East Antarctic ice sheet^{5,7}; disintegration of the West Antarctic ice sheet would increase sea level by only ~4 m (refs 8, 9).

The only physical mechanism which seems capable of initiating a surge of the East Antarctic ice dome, or major portions thereof, is creep instability due to frictional heating at the base of a deforming ice sheet 10-16. Such an instability could cause massive melting at the base of the ice sheet on a very rapid time scale and allow the ice to slide freely over the underlying bedrock. The possibility of melting by shear heating is a consequence of the strong temperature T dependence of the rheology of ice. Frictional heating in the basal shear layer of the ice sheet tends to raise the basal temperature and reduce the viscosity near the base. If the thickness of the ice sheet remains constant, so will the basal shear stress, and the increase in temperature and decrease in viscosity will tend to increase

the rate of frictional heating. Enhanced heating will further increase the temperature in a potentially unstable manner. Shear heating instability can occur if the ice sheet thickness h exceeds a critical value h. in which case steady, subsolidus sliding of the ice sheet is not possible 15

The scenario we develop calls on climatically enhanced accumulation to increase the thickness of the East Antarctic ice sheet above the critical value necessary for the onset of explosive creep instability. The climatic change could be a consequence of latitude-dependent variations in solar insolation that accompany changes in the Earth's orbital motion. Thus our model may provide a link between the astronomical 17,18 and Antarctic surge theories for the inception of ice ages by using the former to initiate the latter. However, if the Antarctic surge phenomenon does have a crucial role then it is not necessary for orbital forcing to cause major spreading of ice sheets. Any climatic occurrence resulting in increased accumulation over Antarctica and a sufficiently large thickening of the Antarctic ice sheet might initiate surging and the onset of an ice age.

Model

The critical thickness h_c required for creep instability and surging can be calculated using a one-dimensional, steady-state, thermomechanical model for the gravitational creep of a constant thickness h ice sheet down a slope making an angle α to the horizontal¹⁵. The coordinate perpendicular to the slope is y; the ice surface is y = 0 and the base is y = h. The surface of the ice and its base have the same slope in this model, while the surface and bedrock slopes of the East Antarctic ice sheet are unequal. This difference between the mathematical model and the real ice sheet is unimportant, however, as the shear stress τ in an ice sheet is mainly determined by the surface slope¹⁹. The distribution of shear stress in our model ice sheet,

$$\tau = -\rho g y \sin \alpha \tag{1}$$

where ρ is the density of ice and g is the acceleration due to gravity, is thus representative of the shear stress in the real ice sheet as long as we equate α with the local surface slope.

The equations governing the temperature T in the model ice sheet and its downslope creep velocity u are 15

$$\frac{\mathrm{d}^2 T}{\mathrm{d}y^2} - \frac{v}{\kappa} \frac{\mathrm{d}T}{\mathrm{d}y} + \frac{2A}{k} \{ \rho gy \sin \alpha \}^4 \exp \left(\frac{-E^*}{RT} \right) = 0 \tag{2}$$

$$\frac{\mathrm{d}u}{\mathrm{d}v} = -2A \{\rho g y \sin \alpha\}^3 \exp\left(\frac{-E^*}{RT}\right) \tag{3}$$

where k is the thermal conductivity and κ is the thermal diffusivity. The temperature equation (2) is a balance between conduction, vertical advection with velocity v, and viscous dissipation. Equation (3) is the creep law of ice²⁰, A is a rheological , A is a rheological parameter, E^* is the activation energy and R is the universal gas constant. The vertical velocity is given by the accumulation rate. We use two models for the y-dependence of $v: v = v_c =$ constant and $v = v_c(1 - y/h)$. The constant v model is preferred because v decreases from v_c to 0 in a thin boundary layer at the base of the ice sheet¹⁵. Equations (2) and (3) are solved subject to the conditions

$$T = T_0, \qquad \text{on } y = 0. \tag{4}$$

$$T = T_0$$
, on $y = 0$. (4)
 $k \frac{dT}{dy} = q_b$, $u = 0$, on $y = h$ (5)

where T_0 is the constant temperature of the ice surface and q_b is the geothermal heat flux entering the base of the ice sheet. We have assumed that there is no basal sliding. This two-point boundary value problem is solved using standard numerical procedures¹⁵.

Parameter values

The East Antarctic ice sheet has surface slopes of 0.05-0.10° and thicknesses of 2-4 km (refs 21-24); accumulation rates are typically 0.03 m yr⁻¹ in the interior and an order of magnitude larger near the coast^{14,25}. Experimental data on the creep of polycrystalline ice suggest that E^* is in the range 60-70 kJ mol⁻¹ at temperatures ≤ -10 °C (refs 26–28). The value of A depends on grain size, impurity content and crystal orientation. We have used $A=8.75\times10^{-13}\,\mathrm{s^{-1}\,Pa^{-3}}$, a value representative of the experimental determinations^{27,28}. We have also used $k=2.5\,\mathrm{W\,m^{-1}\,K^{-1}}$, $\kappa=1.3\,\mathrm{mm^2\,s^{-1}}$, $\rho=900\,\mathrm{kg\,m^{-3}}$, $g=9.8\,\mathrm{m\,s^{-2}}$, $T_0=223\,\mathrm{K}$, and $q_b=40\,\mathrm{mW\,m^{-2}}$. The value of T_0 is representative. tive of the annually averaged surface temperature in the interior of East Antarctica and the value of q_b is a typical continental heat flux29.

Critical thickness for shear heating instability

Nonlinear coupling between velocity and temperature results in the solution curves shown in Fig. 1 for $E^* = 60 \text{ kJ mol}^{-1}$. For given α and v_c there is a maximum thickness h_c for which steady creep is possible. The dashed portions of the curves indicate solutions which have basal temperatures at or above the melting temperature of ice. The maximum thickness increases with increasing accumulation rate (Fig. 1a) because downward advection of cold ice to the basal shear zone enhances the

importance of frictional heating. For the same reason, h_c in the constant v model is larger than it is in the situation where v decreases linearly with depth (Fig. 1b). A decrease in α also leads to an increase in h_c (Fig. 1c) because large ice thicknesses are then necessary to produce the shear stresses required for internal deformation. Basal temperatures for the supercritical states are generally at or above the melting point of ice. Even the subcritical states have basal melting when the ice thickness is large. The tendency of downward advection to lower basal temperatures is more than compensated by the associated increase in viscous dissipation.

Figure 2 shows the dependence of the maximum thickness on activation energy; h_o increases approximately exponentially with E^* for given α and v_c . The thicknesses within the East Antarctic ice sheet (2–4 km) are near the calculated values of h_o for $\alpha=0.1^\circ$, $v_o=0.03$ m yr⁻¹ and E^* between 60 and 70 kJ mol⁻¹.

Occurrence of instability and surging

The existence of a maximum thickness for which steady, stable, subsolidus, gravitational sliding of an ice sheet is possible is the fundamental reason for the occurrence of catastrophic shear heating instability. According to Fig. 2, for example, an ice sheet on a 0.1° slope would creep down hill in a steady, stable manner if its thickness were ≤5 km for an activation energy of 70 kJ mol⁻¹ and an accumulation rate of 0.03 m yr⁻¹. However, if its thickness were suddenly increased above 5 km by a rapid climatically enhanced accumulation it could no longer slide stably. An instability would occur in which frictional heating near the base of the ice would result in massive melting and a surge of the ice sheet, as shown in Fig. 3. The maximum thickness of the East Antarctic ice sheet is ~4 km, its activation energy may be $\sim 70 \text{ kJ mol}^{-1}$, surface slopes of about 0.1° occur over widespread areas, and typical accumulation rates are 0.03 m yr⁻¹. Thus it is possible that the East Antarctic ice sheet lies close to the point of creep instability.

The occurrence of shear heating instability and surging in response to a rapid increase in ice thickness $h > h_{\rm c}$ is a consequence of the super-exponential time scale on which thermal runaways of this nature take place³⁰. The growth times for such explosive finite-amplitude instabilities far exceed those calculated on the basis of linear theory^{31,32}. The very rapid growth of the instability limits the time available for the ice sheet to self adjust to the increase in accumulation in ways that might avoid instability. For example, if the flux could be maintained constant by thinning the ice sheet, it would be stabilized, because the solutions for flows subjected to a constant flux

boundary condition are single-valued in contrast to the multivalued solutions occurring for the constant thickness boundary condition^{33,34}. However, the sudden enhancement in accumulation is externally imposed, the ice sheet must thicken initially, and the catastrophic occurrence of shear heating instability precludes self adjustment and the maintenance of constant flux^{35,36}. Simple energy arguments support the reality of the instability³⁷.

The fast time scale associated with finite-amplitude shear heating instability is essential to ice sheet surging on a continental scale; the isotopic evidence⁶ for rapid surging at the end of the last interglacial has already been cited. It is probably not feasible for basal melting in subcritical conditions to lead to large-scale disintegration of the Antarctic ice sheet, as originally suggested by Wilson¹, because there is no fast time scale involved. The ice sheet has sufficient time to flow and accommodate itself to changing surface conditions so as to preclude massive collapse by large-scale decoupling between the ice and the bedrock. This is supported by inferences from modelling^{38,39} and the discoveries of large sub-ice lakes23 that large areas of the base of the East Antarctic ice sheet are at the melting temperature. Despite this, the ice sheet is apparently stable. This does not preclude localized basal sliding or surging due to melting by shear heating. Basal sliding at the rate of 10 m yr⁻¹ has been reported for the ice sheet in the Mizuko Plateau⁴⁰.

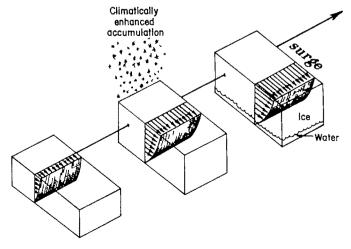

Fig. 3 Sketch of the events leading to shear heating instability and surging of the East Antarctic ice sheet.

for example. Such localized sliding contributes to the global stabilization of the present ice sheet.

The above modelling results suggest that past ice ages may have been caused by shear heating instability of the East Antarctic ice sheet. A climatically enhanced accumulation is required to thicken the ice beyond its maximum thickness for stable, steady, gravitational sliding. Any climatic event which enhances accumulation over Antarctica would suffice to initiate the process; variations in the Earth's orbital motion or enhanced volcanic activity are possibilities. The thickening of the ice must occur quickly so that flow within the ice cannot lead to an

accommodation and stabilization of the ice sheet against the changing conditions. Instability and large-scale melting must occur extremely fast for the same reasons. Because shear heating instability is explosive in nature, such fast collapse of the ice sheet should be possible. Theoretical calculations of the super-exponential growth rates accompanying these catastrophic instabilities yield the necessary fast time scales.

Is the Sun an oblique magnetic rotator?

G. R. Isaak

Department of Physics, University of Birmingham, PO Box 363, Birmingham B15 2TT, UK

The recent observation of rotational splitting of the non-radial p modes of l=1 and l=2 (with $n\sim 20$) of the 5-min global oscillation of the Sun was interpreted in terms of rotational splitting associated with a rapid rotation of the solar interior. The precise value deduced for the angular velocity Ω of the interior depends on the assumed variation of Ω with depth and on the weighting function. Thus with a weighting function² of the form

$$\bar{\Omega} = \int \frac{\Omega(r)}{V(r)} dr \int \frac{dr}{V(r)}$$
 (1)

where V(r) is the local velocity of sound at radius r, one obtains values of $\Omega_{\rm core}/\Omega_{\rm surface}$ ranging from 2 to 9 as the radius at which Ω , assumed to be constant for smaller r, ranges from 0.6 to 0.15 of the solar radius. Such a weighting function proportional to the time the wave spends at any particular radius seems very plausible for the effect of any parameter, be it angular velocity or magnetic field, on the propagation of nearly plane waves as they bounce between the centre and the surface. Here I attempt to correlate the size of the observed rotational splitting with the enigmatic 12.2-day variation in the measurement of solar oblateness discovered by Dicke³ previously⁴ and to interpret the observed near equality of the amplitudes of the m-components of the l=1 and l=2 rotationally split modes. This leads to the first empirical evidence that an asymmetric magnetic rotator with megagauss magnetic fields exists in the interior of the Sun. It also suggests that the magnetic energy of young stars is a sizeable fraction of their gravitational energy.

I speculate, together with Dicke³, that this observed periodicity and the rotational period of the core of the Sun are identical.

This assumption allows one to refine the model of the solar interior by demanding that up to a radius r the Sun rotates uniformly, say, at the sidereal rate of 0.95 µHz (corresponding to 12.2-days) and beyond that radius at the surface rate of 0.46 µHz and that the integral (1) equals the observed rotational splitting of about 0.78 µHz (sidereal). On the above assumptions the integral can be satisfied for a current solar model' with the boundary at $r = 0.9 R_{\odot}$. It is natural to speculate that this value corresponding to the boundary between the rapidly rotating core and the slowly rotating surface layers does measure the depth of the convection zone. A slower transition from the rapidly rotating core to the more slowly rotating surface layers would imply a deeper convection zone.

The observation of l=1 triplets with nearly equal components (and less conclusively l=2 quintuplets with nearly equal components) does not accord with the expectation of purely rotational splitting of solar modes being viewed from Earth nearly along the solar equator. Thus, excluding the possibility of frequent excitation from randomly distributed sources and a correspondingly large damping, the expected skew symmetry of the central m=0 component about the solar equator would lead one to expect that the m=0 component ought to be absent in a global view of the Sun and very weak for a tilt of the solar equator of some 6° with respect to that condition as obtains during the observing period.

The presence of this component strongly suggests a perturbation which makes a large angle with the axis of rotation and rotates the angular distribution pattern through a substantial angle. Although purely hydrodynamic effects⁶ at the boundary between the rapidly rotating core and the slower outer layer could be responsible the required velocities would have to be high (~1 km s⁻¹) and in substantially different directions from those of the rotating matter. I, therefore, suggest that the perturbation is magnetic and in the absence of a theory of the combined action of rotation and magnetic field on frequencies of oscillations, that the analogy between rotational and magnetic splittings in an acoustic spectrum and magnetic and quadrupole splittings of atomic and nuclear energy levels be explored.

Such considerations suggest that an intense internal magnetic field, such as might be associated with an oblique (asymmetric?) magnetic rotator, could be responsible for the perturbation. Assuming a linear superposition of rotational and magnetic effects leads one to expect^{7,8} frequency shifts $\Delta \nu_{n,l,m}$ superimposed on acoustic frequencies ν of the order of

$$\left(\frac{\Delta \nu}{\nu}\right)_{n,l,m} = \alpha_{n,l,m} \frac{E_{\rm M}}{|E_{\rm G}|} \tag{2}$$

where $E_{\rm M}$ is the magnetic energy and $E_{\rm G}$ the gravitational energy of the Sun and $\alpha_{n,l,m}$ is of the order of unity and depends on the precise configuration of the magnetic fields and on the mode (n, l, m). The positions of the unshifted lines cannot be measured nor, at present, calculated. Upper limits on the magnetic energy can, nevertheless, be estimated through equation (2) from the symmetry of the observed multiplets together with the assumption that the obliqueness angle with respect to the rotational axis is near 90° (ref. 3). The l=1 triplets, observed between n=16 and n=26, are symmetric to within the measured linewidth of 0.6 µHz that is

$$\delta(\overline{\Delta\nu_{n,l}}) = \langle |\nu_{n,l,0} - \frac{1}{2}(\nu_{n,l,1} + \nu_{n,l,-1})| \rangle \le 0.6 \times 10^{-6} \text{ Hz}$$
 (3)

This implies that for $|E_{\rm G}|=6\times10^{48}\,{\rm erg}$ and $E_{\rm M}=(B^2/8\,\pi)\,\bar{V}$ where B is the magnetic field and \bar{V} is the volume of the Sun, excluding the convection zone, $\langle B^2\rangle_{\rm max}^{1/2}=3.3\times10^6\,{\rm G}$, if

$$\overline{\Delta \alpha} = \langle |\alpha_{n,l,0} - \frac{1}{2}(\alpha_{n,l,1} + \alpha_{n,l-1})| \rangle = 1 \tag{4}$$

whereas if $\Delta \alpha$ is substantially below unity the upper limit will be correspondingly higher.

A lower limit is given by demanding that the angular distribution rotates during the observation time $\tau = 28$ days by at least 1 rad that is $2\pi\Delta\nu\tau > 1$, yielding a lower limit $\langle B^2 \rangle_{min}^{1/2} =$ 1.1×10^6 G, if $\alpha = 1$.

If the earlier identification concerning the significance of the 12.2-day variation in the measurement of solar oblateness is assumed the value τ ought to be reduced to 12 days and $2\pi\Delta\nu\tau > 1$ yields $\langle B^2\rangle_{\rm mm}^{1/2} = 1.7 \times 10^6$ G, if $\alpha = 1$.

The observable effects of the magnetic field are, of course, weighted over the solar interior and this would be expressed in the size of the factor $\alpha_{n,l,m}$. In the absence of such model calculations one might put $\alpha_{n,l,m} = 1$ as a crude approximation and weight the square of the magnetic field in the solar interior $B^{2}(r)$ with a weighting function of the form of equation (1). Rough calculations show that the resultant is an observable mean square magnetic field which is smaller or larger than the volume averaged $B^{2}(r)$ depending on whether the field is extended or decreases rapidly (for example, as the matter density) with radius.

Speculations concerning large internal magnetic fields have been made before⁹⁻¹¹ but this is the first clear empirical evidence pertaining to the interior of the Sun which suggests their presence.

Such intense fields presumably have a fossil origin⁹. Although such fields are but a small fraction of the maximum fields allowed by the extended virial theorem¹², the much higher angular velocities of young solar type stars¹³ suggest that this may not have been the case in the early evolutionary stages of the Sun and presumably other main sequence stars. The magnetic flux, and therefore the internal field, is likely to be decreasing with time because of ohmic dissipation and also because of flux loss and angular momentum loss through the surface layers through the solar wind^{10,14,15}. In the early life of the Sun the magnetic energy may have been a non-negligible fraction of the total energy of the star.

Although the magnetic fields in the solar core considered above are large their contribution to the pressure in the core is likely to be too small to be significant in the context of the solar neutrino problem¹⁶.

The mixing that such magnetic fields are likely to provide 10 will, however, probably also solve the problems of the missing solar neutrinos 17,18 as well as the Earth's climatic problems caused by an ancient cool Sun19.

The asymmetric oblique magnetic rotator has a nutation frequency ω given by

$$\frac{\omega}{\Omega} \simeq \frac{E_{\rm M}}{|E_{\rm G}|} = \frac{1}{\Delta \bar{\alpha}} \frac{\delta(\overline{\Delta \nu_{nl}})}{\nu_{nl}} \leqslant \frac{1}{\Delta \bar{\alpha}} \frac{0.6 \text{ } \mu\text{Hz}}{3 \text{ mHz}} \leqslant \frac{1}{\Delta \bar{\alpha}} 2 \times 10^{-4}$$

where Ω is the angular velocity of the core taken to be $6\times$ 10⁻⁶ s⁻¹. Thus the period of one nutation should be longer than 166 $\Delta \alpha$ yr and as $\Delta \bar{\alpha}$ is likely to be <1 it is tempting to speculate, together with Dicke²⁰, that this corresponds to the 22-yr solar cycle. With this identification, the magnetic energy of the Sun would be increased above the value given by equation (4) and $\langle B^2 \rangle^{1/2}$ would be 9×10^6 G.

Other aspects of solar activity which seem to be explained by the above model will be discussed elsewhere.

If the above ideas concerning internal magnetic fields correspond to reality the Sun will fit quite naturally into the sequence of young Ap stars to white dwarfs and pulsars. Moreover the Sun will be able to sustain a very much richer spectrum of modes of vibration and it is conceivable that the 160-min oscillation^{21,22} is such a magnetohydrodynamic mode.

The magnetic effects should give rise to asymmetries which will be detectable with the higher resolution of longer strings of velocity measurements in the near future and may also produce periodic displacements with 12.2 or 6.1-day periods.

If the Sun has substantial magnetic fields in the core it is tempting to speculate that other stars also do and it is suggested that the β Cephei stars, for example, show large magnetic rather than rotational splittings and the magnetic fields may destabilize the stars sufficiently²³ to make them pulsate.

I thank Professor H. H. Voigt for the hospitality and the Akademie der Wissenschaften for support during my stay in Göttingen.

Inferring solar UV variability from the atmospheric tide

Neill S. Cooper

Atmospheric Physics Group, Department of Physics, Imperial College, London SW7 2BZ, UK

A new method of determining variations in the solar UV output is presented here. The method is based on the fact that the semi-diurnal (12 h) atmospheric tide is dominated by the component forced by ozone absorption of UV. This tide shows very little interannual variability; hence a variation in UV of 20%, as suggested by Heath and Thekaekara¹, would have an easily discernable effect on the tide. It can be shown that a change of 20% in UV would result in a 12% change in the semi-diurnal tide. The failure to find any solar cycle-related variation in the semi-diurnal tide suggests that the UV varies by <2% over the sunspot cycle.

The suggestion that the solar UV output varies by ~20% over the 11 yr sunspot cycle is controversial^{2,3}. Such changes in UV would alter ozone concentrations, temperature and wind in the stratosphere^{4,5}. This may affect the vertical propagation of planetary waves in winter^{6,7} and hence the troposphere. One indicator of ozone layer heating whose variation over the sunspot cycle is on record, but which has received little attention. is the semi-diurnal (12 h) atmospheric tide. Unlike oceanic tides, this is due to the heating effect of the Sun8. The dominant component is from ozone absorption of UV 8.

The model of atmospheric tides used here is that of Chapman and Lindzen⁸. The altitudinal and latitudinal dependences are separated. The latitudinal variation of the tides are Hough functions and the vertical structure equation, with appropriate boundary conditions, determines the magnitude and phase of each component of the tide at all levels. The effect of zonal winds and the interaction between different tidal components are ignored, which results in an underestimate of the amplitudes 5,10. The only forcings considered were the heatings due to ozone and water vapour absorbing solar radiation. The heating profiles were obtained using a model similar to that of Forbes and Garrett11.

Data were obtained from two sources of 'hourly averaged annual pressure', that is, the mean pressure at each hour of the day averaged over 1 yr. Results for Macau were from Resultados das Observações Meteorológicas, 1952-78, while the Indian values were from Indian Weather Reviews, Annual

Table 1 Details of the tropical stations

Station	Loc	ation	Years used	Total (yr)
Bombay	18.9° N	72.8° E	1948-54, 1956-62	14
Calcutta	22.5° N	88.3° E	1948–54, 1956–63	15
Macau	22.2° N	113.6° E	1952-1975	24
Madras	13.1° N	80.3° E	1951-54, 1956-61	10
Nagpur	28.6° N	79.1° E	1949-54, 1956, 1948-63	13
New Delhi	18.5° N	77.2° E	1949-53, 1956-63	13
Poona	4.6° S	73.9° E	1948-54, 1956-62	14
Seychelles		55.5°E	1951–54	4

Summaries, 1948-63. Table 1 lists the eight stations used, their locations and the years for which their data were available.

The amplitudes of the mean tides, averaged over the 107 station years, are 0.809 mbar (diurnal) and 1.180 mbar (semidiurnal). These are larger than the values the theory predicts, as a result of ozone and water vapour forcing alone, by factors of 5 and 1.6 respectively. This result is consistent with that of previous work in atmospheric tidal modelling^{8,10}. The causes of the disagreement between theory and observation are the approximation of linearity in the theory^{9,10}, and the neglect of local tropospheric heat sources^{12,13}. The latter is particularly evident in the diurnal tide, which is much larger over the continents than over the oceans.

Having obtained results for mean conditions, the heating profile is then altered by changing UV and ozone concentrations to examine the effect of UV variability. The ozone concentration is altered, due to changes in UV, by the amount predicted by stratospheric models^{4,5}. This has a negligible effect on the tides, as there is complete absorption of UV by ozone. The UV variation over the sunspot cycle is parameterized by a $\pm 10\%$ variation in the ozone heating in the Hartley Band, Huggins Band and Hertzberg continuum. The model predicts a change of $\pm 6.2\%$ in the semi-diurnal tide in the tropics, while the diurnal (24 h) tide would vary by $\pm 0.8\%$. It is assumed that the component of the tides unexplained by the theory has the same fractional change with UV variation as the theoretical component. As the semi-diurnal tide shows very little annual variation, a change of 12% would be readily visible.

Table 2 The mean tide, and the predicted and observed increase in the amplitude from sunspot minimum to sunspot maximum

	Diurnal (µbar)	Semi-diurnal (µbar)
Mean	809	1,180
Predicted	14	148
Observed	-41 ± 13	5±11

Results are from the stations listed in Table 1. The error estimates are one standard error.

The results for all the stations are considered together to reduce the standard errors. They are normalized at each station, before averaging over all the stations, so that changes solely in amplitude add together linearly and not vectorially.

The results are shown in Table 2 which highlights the discrepancies between the theoretical predictions and the observations. The diurnal tide shows a much larger variation (-41 \pm 13 µbar) over the sunspot cycle than predicted (14 µbar). The semi-diurnal tide, on the other hand, is predicted to increase by 48 μ bar but is observed to increase by only $5 \pm 11~\mu$ bar. This latter result agrees with previous work¹⁴, where no correlation was found between sunspot activity and the amplitude of the semi-diurnal tide at Batavia (for 1866-1945) and at Manila (1890-1938).

The variation in the diurnal tide is actually larger than the whole component forced by ozone heating, thus it is unlikely to be due to variations in UV. Hence, between 1948 and 1975 there was a diurnally varying tropospheric parameter which had a significant change over the sunspot cycle. However, where a significant change was expected, in the semi-diurnal tide, none was found. The observations of this tide provide an estimate of the maximum value for the sunspot cycle variation in UV. As shown above, a 20% change in the UV would cause a 12.3% change in the semi-diurnal tide, so assuming linearity, the observed tidal variation is due to a $0.5\% \pm 1.6\%$ variation in the UV. This result is more precise than any derived using conventional techniques³. Analysis of a larger surface pressure data set may lead to even greater precision.

This result shows that the atmospheric semi-diurnal tide can be used to examine possible solar UV variations. Indeed, this tide may also be usable for remote sensing of the stratosphere, in a way analogous to those for examining the internal structure of the Earth¹⁵ and Sun¹⁶. If this is the case, the large exant quantity of hourly surface pressure data might be used to determine possible stratospheric variations (unrelated to solar activity) over the past 100 yr.

I thank other members of the Atmospheric Physics Group at Imperial College for their support, particularly Dr J. S. A. Green, also the Meteorological Office Library for providing data. The work was financed by the NERC and the Appleton Laboratory.

Diurnal variation of mesospheric ozone

G. Vaughan

Meteorological Office, Bracknell, Berkshire RG12 2SZ, UK

Photochemical models¹⁻³ predict a considerable variation in ozone concentration between day and night in the mesosphere. To investigate this, four Petrel rockets were flown from South Uist (57°22'N, 7°22'W) on 2 October 1979. Ozone was measured by observing the atmospheric attenuation of a narrow band of UV radiation, using interference filters to define a bandwidth of ~10 nm. The rockets were launched (1) at moonset, 02,00h, (2) at sunrise, 06,00h, (3) at 09,30h and (4) at 15.30h; round 1 observing moonlight and the other three observing sunlight. The first two used the occultation technique and contained two photometers with wavebands centred around 265 and 290 nm (Fig. 1), giving ozone information from 48 to 95 km. For rounds 3 and 4 the Sun was at a zenith angle of 70°, and a single waveband centred around 265 nm gave a height range of 44 to 64 km. Full details of the experiment will be published elsewhere. The first three rounds were successful, but the fourth did not give good data because the rocket nosecone failed to clear the field of view. The results show significant diurnal variation above 54 km, which exceeds a factor of 2 above 65 km and reaches a factor of 10 between night time and sunrise at 90 km.

To retrieve ozone density from the raw flight data, a profile was produced of attenuation as a function of height for each sensor. The signals near apogee showed no drift in detector sensitivity, but rounds 2 and 3 showed some dependence on rocket attitude (coning modulation). The observations near apogee were used to derive corrections for this, and to deduce the unattenuated signals for the rest of the flights. The attenuation profiles were completed by using a radar track of the first 64 s of flight, extrapolated using a ballistic trajectory, to give rocket height.

For zenith angle 70°, the transmission $\xi(h)$ at height h may be written

$$\xi(h) = \frac{\int d\lambda I_0(\lambda) S(\lambda) \exp{-\{\sigma_{ox}(\lambda) N_{ox}(h) + \sigma_{R}(\lambda) N_{aur}(h)\}}}{\int d\lambda I_0(\lambda) S(\lambda)}$$
(1)

where I_0 is the unattenuated source irradiance at wavelength λ , $S(\lambda)$ the sensor sensitivity, $\sigma_{cx}(\lambda)$ the ozone absorption coefficient and $N_{cx}(h)$ the path total of ozone molecules between rocket and source. σ_R and N_{air} refer to Rayleigh scattering by air molecules. This equation may be solved for each value of ξ to obtain $N_{ox}(h)$, and the number density $n_{ox}(h)$ (given by

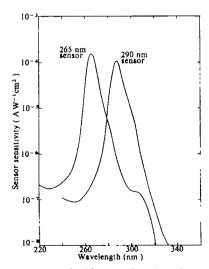

Fig. 1 Photometer sensitivities as a function of wavelength for round 2.

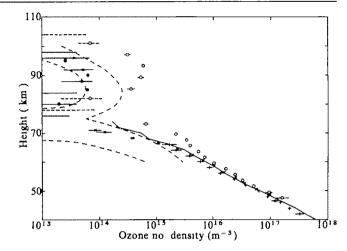

Fig. 2 Ozone number densities as a function of height. Error bars are random standard errors for the present measurements, and χ is the zenith angle of the centre of the Sun or Moon, viewed from the rocket. \bigcirc , 02.00h, $\chi = 94.5$ (Moon); \times , 06.00h, $\chi = 95.5$ (Sun); +, 09.30h, $\chi = 69.7$ (sun); —, daytime from ref. 14; \bigcirc , sunset from ref. 4; \bigcirc -, envelope of night-time values from ref. 16.

 $-\cos\theta \, dN_{cx}/dh$ for zenith angle θ) may then be obtained by differentiating equation (1) with respect to h. The raw attenuation values for round 3 were smoothed by fitting a quadratic curve over 4-km intervals (about 30 individual observations), which also gave $d\xi/dh$ with its statistical standard error.

For rounds 1 and 2, the attenuation profile was first expressed as a function of tangent ray height. Because of the finite angular size of the Sun and Moon the attenuation at the rocket was a smoothed version of that from a point source. $N_{\rm oz}(h)$ was retrieved at discrete levels assuming constant scale height between levels, by an iterative process similar to that described by Miller and Ryder⁴ and Miller⁵. Standard errors in $N_{\rm oz}(h)$ were obtained by calculating the covariance matrix.

To deduce number densities from the path totals, ozone was assumed constant in a series of concentric layers, thus the path totals N(h) could be written ${}_{1}\Sigma L_{1}(h)n_{1}$ where $L_{1}(h)$ is the length of the path through the *i*th layer and n_{1} the number density there. The inversion of this problem is very sensitive to noise in N(h) and the method described by Rodgers⁶ was used to stabilize the solution without introducing appreciable bias. This involved using an 'a priori constraint' composed of a hand-smoothed version of an unconstrained retrieval. Below 70 km, ozone number densities were retrieved for 1 km layers but to stabilize the solution above 70 km, layers 4-km thick had to be used. In each case standard errors were obtained by calculating the covariance matrix.

For each sensor, the solar spectrum used was that of Broadfoot⁷ below 300 nm and Simon⁸ for wavelengths above 300 nm. Ozone absorption coefficients were taken from Inn and Tanaka⁹, corrected for temperature after Vigroux¹⁰. Rayleigh scattering was calculated using Penndorf's¹¹ value for cross-section, and the atmospheric profile provided by the Stratospheric and Mesospheric Sounder (SAMS) on the Nimbus 7 satellite (J. J. Barnett, personal communication). Solar limb darkening was calculated from data given by Moe and Milone¹².

Round 3 produced only one ozone profile, on the ascent leg, but rounds 1 and 2 also gave profiles on the descent leg. However, because of the need to extrapolate the radar data beyond 64 s, there is considerable uncertainty in the rocket position on the descent, and data from the ascents only are presented, with a height uncertainty of ~ 250 m. (These profiles were in good agreement with those of the descents.) The results are presented as number densities in Fig. 2 and mixing ratios in Fig. 3, atmospheric density being calculated from SAMS temperatures, extended above 75 km with the CIRA $(1972)^{13}$ standard atmosphere for 60° N. Values shown are from the 290 nm sensors below 64 km and from the 265 nm sensors

above this height. For rounds 1 and 2 the height resolution is ~ 5 km, and for round 3, ~ 4 km.

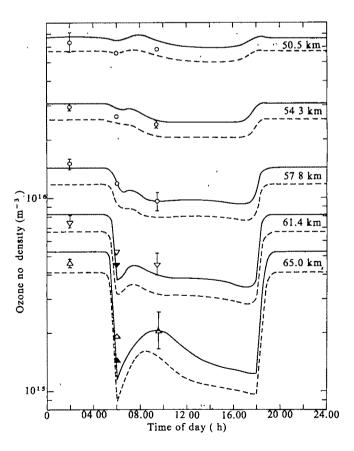

Errors in the ozone absorption coefficient (especially the temperature correction) and the spectral calibration contribute most of the systematic uncertainties in the results; the former amount to $\sim 4\%$ and the latter to 2% increasing to 5% below 48 km. Below 70 km for the dawn round, a test was made of the sensitivity of the retrieval to the hypothesis of horizontal uniformity, as ozone is predicted to vary rapidly near the terminator above 60 km. The photochemical model described below was used to predict the ratio of the concentration in each layer to its value at 90° zenith angle, and these ratios were incorporated in the retrieval. The differences from the original profile are shown in Fig. 3—they increase from $\sim 5\%$ at 58 km to a maximum of 28% at 67 km.

The results show a significant day-night difference in ozone concentration above 53 km, which reaches a factor of 10 above 70 km. The retrieval technique was unable to give more than an upper limit on the ozone amounts in the 'dip' of the profiles around 78 km, but the large differences persist in the upper ozone layer around 90 km. The dawn and morning profiles agree with Krueger and Minzner's¹⁴ (45° N, daytime) standard midlatitude ozone model between 46 and 66 km, and the dawn values above 80 km agree well with those of Miller and Ryder⁴ (58° N, September, sunset) and Llewellyn and Witt¹⁵ (68° N, March, sunset, not shown on Fig. 2). The night-time measurements are compared above 60 km with the envelope of equatorial profiles obtained using stellar occultation by Hays

and Roble¹⁶. Unlike the present values, these show a divergence from the Krueger and Minzner¹⁴ model below 65 km, which is not supported by other workers^{17,18}. Above 65 km, our values are the greater at all altitudes, with a peak concentration 9 km higher, possibly due to the difference in latitude.

Previous measurements of the day-night difference of ozone below 65 km have been reported by Hilsenrath¹⁹ (38° N, March) and Anderson *et al.*²⁰ (50° S, December), both of whom show a factor of 2 at 65 km, in agreement with the present work. The change in column total above 50 km of 10¹⁶ molecules cm⁻² agrees with the measurement of Penfield²¹, even though the profiles he showed were very different from ours. Above 70 km, our night-time column total of $1.24 \pm 0.07 \times 10^{15}$ cm⁻ agrees well with that of Wilson and Schwartz²², who report $1.1\pm0.4\times10^{15}$ cm⁻². These authors, like Penfield, used groundbased microwave spectroscopy, which has the disadvantage of poor height resolution (~20 km below 70 km), precluding a direct comparison with our measurements at specific heights. However, they show no sign of the minimum in ozone concentration around dawn and small maximum in mid-morning above 65 km as predicted by theory (see below). In contrast, the present measurements show the dawn profile crossing that at 09.30 near 65 km, indicative of just such a feature.

Above 80 km, there have been no coincident measurements of day and night ozone profiles to compare with this work. Model predictions of day-night differences in this region vary considerably, and depend on the value adopted for the vertical diffusion coefficient¹. Hunt²³ predicts a night-time enhancement factor of 2 and Shimazaki and Laird² predict 100. Theoretical predictions below 70 km are less variable but a quantitative comparison between theory and experiment requires a model run at the same latitude with the same profiles of relevant atmospheric variables. Comparison will therefore be made with

Flg. 4 Comparison between observations and theory Solid lines are theoretical calculations with 2 p.p.m. water vapour and the broken lines correspond to 4 p.p.m. water vapour. Open symbols at dawn refer to retrievals assuming symmetry and closed symbols refer to retrievals with variable ozone (see text and Fig. 3).

a one-dimensional model adapted from the Oxford University two-dimensional model²⁴. This integrates the photochemical continuity equations diurnally (with no transport processes) for the odd oxygen, hydrogen, nitrogen and chlorine active species and their associated reservoirs, using rate constants as given in JPL 81.3 (ref. 25). A basic timestep of 5 min (less around dusk and dawn) is used for levels half a scale height (~4 km) apart in the vertical. For this work, the solar spectrum and absorption coefficients were based on the recommendations of Nicolet 26,27 with the parameterization of Frederick and Hudson²⁸ being used for water vapour photodissociation. Temperatures were taken from SAMS data, the latitude fixed at 57° N and the time of year at equinox. A full description of the modelling work will be published elsewhere.

Two sets of model calculations, corresponding to water vapour mixing ratios of 2 and 4 p.p.m., are compared with the observations in Fig. 4. The basic day-night difference in ozone above 55 km is caused by the recombination of atomic oxygen to form ozone at dusk $(O+O_2+M\rightarrow O_3+M)$ and its formation by ozone photodissociation at dawn. The small peak in midmorning above 60 km results from the depletion of water dissociation products (H, OH, HO₂) during the night and their slow release from water during the morning; these products are the main destruction agents for odd oxygen in the mesosphere.

The agreement between theory and observation is consistent with a water vapour mixing ratio profile falling from ~ 3 p.p.m. at 50 km to \sim 2 p.p.m. at 65 km. The magnitude of the diurnal variation (which is relatively insensitive to the water vapour) is overestimated at the upper levels by $\sim 15\%$, possibly due to uncertainties in the rate constants used—the quoted uncertainty²⁵ for the rate of $O+O_2+M\rightarrow O_3+M$, for instance, is enough to account for this discrepancy. It may be concluded, then, that the observations are in agreement with current photochemical theory (given the uncertainty in the latter) provided that mesospheric water vapour abundances of 2-3 p.p.m. are accepted. Recent measurements of this quantity have varied from 1.5 p.p.m. (ref. 29) to 15 p.p.m. (ref. 30) at 60 km, and this work supports a mixing ratio near to the lower end of this

I thank J. H. Seymour for work on the design and preparation of the experiments, also S. G. Palmer and F. H. Price for contributions to the data analysis, and D. E. Miller for support and advice.

'Paradoxical' mechanics under fluid flow

J. M. T. Thompson

Department of Civil Englneering, University College London, Gower Street, London WC1E 6BT, UK

Interest in the fluid loading of engineering structures has been stimulated by acute technological problems arising in the exloitation of off-shore oil fields. Here slender riser pipes, and complete tethered-buoyant platforms must be designed against potentially dangerous instabilities. We show here how conventional structural theorems can be not only violated, but actually reversed under fluid loading due to its essentially non-conservative character. Under increasing flow, for example, the stiffness of an elastic structure can increase, pass through infinity, and become negative. Surprisingly, the negative stiffness domain is stable, but can be destabilized by the addition of a constraint. Experiments on a hanging articulated pipe conveying fluid nicely confirm the theory.

Suppose we are given a black box with a tray hanging beneath it. We add a small mass m to the tray, and it rises a small ce h: we add a second mass m and it rises a further distance h. To our surprise, we find that we can plot a complete stable load-deflection curve with negative stiffness using dead weight loading. What is in the box?

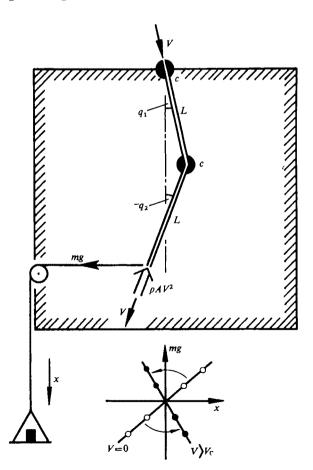

Fig. 1 Articulated pipe system in a box, exhibiting stable negative stiffness under dead loading. The specific details of the system relate to the theoretical study and are not essential. The lengths and stiffnesses need not be the same, and the phenomenon can indeed be exhibited by a continuously flexible hanging hose pipe.

3

Now a local negative stiffness is quite common in structural mechanics, being, for example, generated by an elastic structure that has lost its initial stability at a fold or limit point: but it is then always associated with unstable equilibrium state under dead load. Indeed, an inverted rigid pendulum in our black box would give an equilibrium path of negative stiffness, but the path would be unstable under dead load: it could only be stabilized and therefore studied experimentally by using a suitable rigid-screw loading device.

We can be quite sure, by a fundamental theorem of structural mechanics¹, that our mysterious black box certainly does not contain a conservative mechanical system.

The answer is that it contains an articulated pipe carrying an internal fluid flow, as studied by Benjamin². Two straight and rigid pipes of length L are pinned elastically to one another and to a fixed support by rotational springs of stiffness c, forming a sort of cantilevered hose pipe, the fluid discharging with velocity V into the atmosphere at the free tip.

The statics of the non-conservative system are no mystery. Ignoring gravity, which is inessential in our present theoretical demonstration, the centrifugal force at the knee is statically equivalent to a follower force of magnitude ρAV^2 at the discharging tip as shown in Fig. 1. Here ρ is the density of the fluid and A is the internal cross-sectional area of the pipes. So for small deflections from the vertical, the linearized equilibrium equations are easily written down in terms of the small angles q_1 and q_2 . Moments about the knee for the lower link give

$$mgL + c(q_2 - q_1) = 0$$

and moments about the support for the whole system give

$$2mgL + cq_1 + FL(q_2 - q_1) = 0$$

while the corresponding deflection of mg is

$$x = -L(q_1 + q_2)$$

Here g is the acceleration due to gravity, and $F = \rho A V^2$. Solving these we find

$$x = -mgL^2(2\rho A V^2 L/c - 5)/c$$

so the flexibility x/m decreases linearly with V^2 passing from positive to negative as V passes through its critical value $V_{\rm C}$

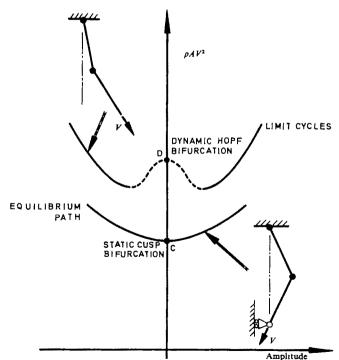

Fig. 2 Buckling (divergence) of a constrained system before the flutter of the corresponding unconstrained system. The dynamic flutter bifurcation is locally sub-critical, but the emerging unstable limit cycles are subsequently stabilized at large deflections.

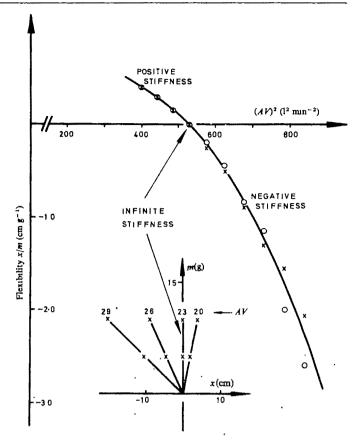

Fig. 3 Experimental results showing a region of stable negative stiffness under dead loading. Infinite stiffness occurs at a critical value of the flow velocity V.

given by setting the expression in brackets to zero. The stiffness m/x therefore increases with V, passes through infinity at $V = V_{\rm C}$ and becomes negative for higher values of V. In all of this, it is to be understood that V is held constant during the stiffness measurements.

So provided the flow velocity is greater than V_c , we have our negative stiffness. The statics is thus easily understood, but why is the system stable at these high velocities? The answer lies in a complete dynamical stability analysis following Benjamin². The displacement-dependent 'follower' force F at the tip is a circulatory force³, being non-conservative and not derivable from a potential energy function: it is represented by a non-symmetric matrix in the lagrangian equations of motion. In addition, the fluid generates velocity-dependent Coriolis forces.

The dynamical study shows that the system is indeed stable for flow velocities up to and above $V_{\rm C}$, stability finally being lost at a dynamic instability at a higher velocity $V_{\rm D}$. This dynamic bifurcation to flutter is of the Hopf type, and on the basis of Lunn's new experiments⁴, the emerging limit cycles are seen to be unstable in the vicinity of the branch, with the form of Fig. 2.

The paradoxical static behaviour arises before the onset of this dynamic instability for $V_C < V < V_D$. It is related to the fact, noted by Benjamin², that if the free end were pinned (but free to move vertically) the resulting single degree of freedom system would buckle (diverge) statically at a flow velocity of $V = V_C$. This single degree of freedom pinned system exhibits a stable-symmetric point of bifurcation (stable cusp) at V_C as shown in Fig. 2, analogous to the behaviour of a continuous pin-ended pipe⁵.

Note here a second paradox. When $V_C < V < V_D$ the addition of a constraint $(q_1 + q_2 = 0)$ destabilizes the system. This cannot occur in a conservative mechanical system. It was observed experimentally by Benjamin² and repeated by Lunn⁴: if the finger is pressed very lightly against the side of the discharging

tip, the pipes buckle like the pinned system pressing strongly and unexpectedly against the finger.

This brings us to the final paradox. The finger is acting like a semi-rigid screw loading device, under which the system is unstable. In the same flow conditions the pipes are stable under dead loading. This is the exact converse of the behaviour of a buckled elastic structure which is stabilized by semi-rigid loading1

Experiments confirming these theoretical deductions are shown in Fig. 3. These used Lunn's experimental pipes, and show the flexibility decreasing with the square of the flow velocity, although not quite in the linear manner of our simple theory which neglected gravitational effects. Perfectly stable equilibrium paths of negative stiffness were obtained in deadloading conditions. The infinite stiffness at $AV = 23 \,\mathrm{l\,min^{-1}}$ is achieved by the structure buckling progressively in its single degree of freedom mode for which $q_1 + q_2 = 0$, thereby giving the reaction ρAV^2 greater and greater leverage about the top support. It is, of course, eventually destroyed by large deflection nonlinear effects.

This new concept of stable negative stiffness explains the strange behaviour discussed qualitatively by Benjamin, and has important implications for the stability and strength analysis of the flexible marine structures now being proposed.

Structural effects in electrocatalysis

R. R. Adžić & A. V. Tripković

Institute of Electrochemistry, ICTM and Centre for Multidisciplinary Studies, University of Belgrade, PO Box 815, Belgrade, Yugoslavia

W. E. O'Grady

Brookhaven National Laboratory, Department of Energy and Environment, Upton, New York 11973, USA

Studies of chemical reactions on well-defined surfaces provide fundamental data on surface reactivity and guidelines for the understanding and design of catalytic materials but few such studies have been done in electrocatalysis. We report here a study of the oxidation kinetics of HCOOH, CH₃OH and CH₂O on single crystal platinum electrodes with (100), (110) and (111) orientations. Pronounced dependence of the kinetics of these reactions on the crystallographic orientation of the surface has been found. The potential regions where reactions take place, the peaks of voltammetry curves, and the magnitude of currents at the peaks are different for each plane. These differences are explained on the basis of adsorption of a strongly bound intermediate, which shows a pronounced dependence on the symmetry of the single crystal planes. This intermediate completely blocks the Pt (100) surface; the smallest adsorption is at the (111) plane. On activation, the (100) surface shows the highest activity. These results suggest that electrocatalytic reactions exhibit structural sensitivity. They also provide guidelines for designing catalysts for the oxidation of small organic molecules to be used in electrochemical energy conversion.

Kinetics of typical electrocatalytic reactions have been studied on poorly characterized high-area supported electrodes and polycrystalline electrodes. Only a few electrosorption reactions have been studied on single crystal surfaces which include hydrogen adsorption¹⁻⁴ and ad-atom formation (underpotential

deposition of metals)⁵. Previous work on the oxidation of HCOOH, CH₂O and CH₃OH has indicated that these reactions 'site-demanding' reactions, requiring specific lattice geometries. Bagotzkii et al.6 showed that in the oxidation of CH₃OH three sites are engaged in adsorption of the intermediate COH. Such reactions will be expected to be sensitive to the structure on (111), (110) and (100) surfaces. The role of specific multiple site requirements was introduced by Balandin⁷ as early as 1929.

The method of preparation and characterization of single crystal surfaces have been described elsewhere8,9. The electrodes were prepared from a Pt single crystal obtained from Materials Research Corporation. The crystals were oriented by Laue back scattering to better than 0.5°. The samples were cut and polished using standard metallurgical techniques and were then slightly etched in boiling aqua regia to remove the work hardened surface. The samples were then annealed at 900 °C for 3-4 h in pure oxygen, reduced at 900 °C for 30 min in hydrogen and cooled over a period of 12 hours in this same atmosphere. They were mounted in Teflon tubing. Immediately before the electrochemical experiment, the electrodes were exposed to 3M HClO₄ to remove possible contaminants such as CaO; they were then rinsed several times with triply distilled H₂O. The electrolyte was 1M HClO₄ prepared from Merck HClO₄ and H₂O prepared by a pyrocatalytic distillation.

Figure 1a shows voltammetry curves for the oxidation of formic acid for three single crystal orientations of Pt. The curves differ substantially in shape and in the magnitude of the currents associated with various peaks. The sweeps in the anodic scan, that is the curves obtained by increasing the potential, show that the highest activity is obtained with the (111) and lowest with the (100) orientation. At the Pt (111) surface the reaction commences at the most negative potential. At the (100) surface the one peak seen sweeping in an anodic direction is usually ascribed to the oxidation of a strongly bound intermediate which blocks the electrode surface for further oxidation of HCOOH. Its oxidation coincides with the onset of oxide formation (100) plane. After activating the surface is this way, the curve obtained by decreasing the applied voltage shows much higher activity. No such effect is seen with the Pt (111) surface: the sweeps almost retrace themselves. This suggests that very little, if any, of the strongly bound intermediate is formed on the (111) plane. The Pt (110) surface shows an intermediate behaviour. Note that the peak in cathodic direction appears at potentials much more positive than the corresponding peak for the (100) plane. Important information is obtained when these curves are compared with that of a polycrystalline electrode. The peak contributions could be correlated with the contributions of the three low Miller index planes. Figure 1b shows a typical voltammetry curve for the oxidation of HCOOH on a polycrystalline platinum electrode. A comparison of the peak potentials on this curve with those obtained for three single crystal orientations (Fig. 1) shows that the first peak in anodic scan (\sim 0.48 V) is characteristic of the (111) plane, and to a lesser degree, of the (110) surface. The second peak in the anodic scan (~0.9 V) is characteristic of the (100) and (110) surfaces. In the cathodic direction, the first peak at 0.7 V is due to the reaction at the (110) surface, while the shoulder at ~0.4 V is characteristic of the (100) plane.

Figure 1c displays voltammograms obtained with methanol. The oxidation commences at 0.5 V at the (111) plane. At the (110) and (100) surfaces the reaction starts at 0.68 and 0.75 V respectively. The largest current is associated with the peak at 0.8 V on the (100) plane. However, from a practical point of view this oxidation takes place at too high a potential because a cell with such electrode would have too low voltage. In that respect, the (111) plane could be considered as the most active catalyst. Note that CH₃OH affects hydrogen adsorption on Pt to a lesser extent than do CH₂O or HCOOH. These data are at variance with the work of Bagotzkii et al.12, who did not find any significant difference between the activity of these single crystal electrodes.

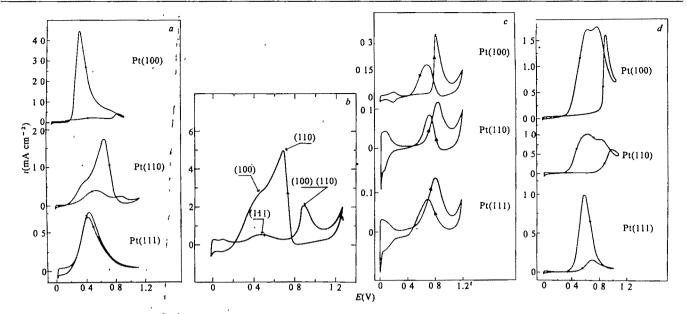

Fig. 1 a, Oxidation of HCOOH (0.26 M) on single crystal Pt electrodes with (100), (110) and (111) orientations in 1 M HClO₄. b, Oxidation of HCOOH on polycrystalline Pt electrode. Assignments of peaks are given in the graph. c, Oxidation of CH₃OH (0.26 M) on single crystal pT electrodes with (100), (110) and (111) orientations. d, Oxidation of CH₂O on single crystal Pt electrodes with (100), (110) and (111) orientations. Sweep rate 50 mVs⁻¹, temperature 22 °C.

The reaction for formaldehyde begins first at the Pt (111) surface, (Fig. 1d) at E = 0.4 V and reaches a peak at E = 0.75 V. At the Pt (100) surface the oxidation commences significantly only at 0.75 V, with the peak at 0.88 V. The current associated with this peak is, however, higher than the current for the (111) and (110) surfaces. After activation of surfaces at the most positive potentials, the sweeps in the cathodic direction show the highest activity on the (100) plane. This shows that strongly bound intermediates in the oxidation of CH2O on Pt are predominantly formed on the (100) and (110) planes.

It is usually assumed that in the oxidation of HCOOH, CH₃OH and CH₂O, which should lead to CO₂, the same strongly bound COH intermediate is formed which blocks the surface, thus decreasing its catalytic activity. Differing activities of the (111), (110) and (100) Pt single crystal electrodes are ascribed to different degrees of adsorption of COH species. Adsorption is lowest on the (111) surface and highest on (100) plane, with (111) orientation generally exhibiting low reactivity. Low hydrogen adsorption on the Pt (111) surface, found by most authors¹⁻³, also has a role in determining the activity of this surface for the oxidation of HCOOH, because adsorbed H participates in the formation of COH. The adsorption and reduction of CO₂ on Pt, which gives the same species, COH, also gives the smallest coverage on the (111) surface 13. This corroborates the above conclusion. Crystallographic anisotropies of the above reactions in many ways mimic those found in the gas phase for CO adsorption¹⁴ on the same crystal planes. CO is the species closest in character to COH, which provides the basis for the comparison of these data.

There are no corresponding studies of adsorption and dehydrogenation of HCOOH, CH₃OH and CH₂O on Pt single crystals. As in the case of CO, the anisotropies which we have found cannot be predicted on the basis of theories of adsorption15 and electrode reactions16 presently available.

On the basis of these data we conclude that the electrochemical oxidation of HCOOH, CH₃OH and CH₂O on Pt exhibits significant crystallographic anisotropies. As these are typical electrocatalytic reactions, which involve a strong adsorption before the charge transfer, these data strongly suggest that most such reactions should show a pronounced structural sensitivity.

Note added in proof: Since submission of this paper, Clavilier et al. 17 have reported similar results.

The process by which ice forms during the cooling of water and aqueous solutions has been studied intensively mostly in conditions where the nucleation occurs heterogeneously-on some particulate impurity surface. When the more fundamental homogeneous process has been deliberately investigated 1-3 it has nearly always been in conditions in which the crystallization

process, once initiated, occurs with great rapidity^{1,2}. Seeking an additional 'degree of freedom' in the investigation of this important phenomenon, we have initiated the crystallization in conditions where the growth is extremely slow and the nucleation events can be controlled. Our observations are described below.

Slow nucleation conditions are obtained by choosing a concentration of water in an electrolyte solution such that the homogeneous nucleation temperature, which may be obtained in separate experiments using emulsions^{2,3}, lies very close to the glass transition temperature. In these conditions the growth of fluctuations to become, first, nuclei and then observable crystals, occurs at a rate which may be varied at will by changing the temperature of observation within a narrow range of a few degrees on either side of the glass transition temperature⁴.

The study of nucleation of ice in such conditions has gained in interest since the observations by A.F.W. and colleagues⁵ of the manner in which crystallization patterns of inorganic high temperature glasses can be influenced by the preceding thermal history. It was demonstrated that, for the appropriate heat treatment, crystallites could be observed growing with correlated spatial distributions with crystallization centres as small as 20 Å in radius and mean separations in the range 200-700 Å depending on thermal history. Since the origin of this phenomenon was not clear at the time (1979), it was clearly of interest to determine whether similar ordered crystal growth could be observed in a different type of system. We therefore undertook a careful study of the development and distribution of crystallites of ice formed in an initially vitreous lithium chloride + D₂O solution, using the small angle neutron scattering (SANS) technique. The conditions for glass formation, and observation of diffusion-controlled nucleation, have been described elsewhere4.

Solutions of 10.5 mol% lithium chloride in D_2O (6.17 m LiCl) were prepared in controlled conditions to avoid the ingress of any light water, H_2O . Samples of the solutions were introduced into a 3-mm space between sapphire windows in a cell whose temperature could be manipulated by a controlled temperature block in which the cell was mounted. The block with cell was then suspended in a liquid helium cooled cryostat which provided the low temperature ambient for the temperature control system. The temperature of the solution was taken to be that of the sapphire window at the edge of the cell, as preliminary experiments had shown that a gradient of <0.1 °C existed between the centre and edge of the sample. The temperature of the cell was monitored during the experiment by a fine chromel/constantin thermocouple in good thermal contact with the window.

The sample was initially vitrified by quenching into liquid nitrogen placed in the bottom of the cryostat and monitoring the temperature to ensure that it did not fall below 130K. Under these circumstances no cracks developed in the sample: the sample remained completely transparent to visible light and caused very little scattering of neutrons. (In some cases where the temperature drop was inadequately controlled, and cracks due to mechanical stress developed, the effects (observed as an excess scattering), could be seen to disappear during the first 2 h of annealing at 139K.)

On the basis of previous observations⁵ of the effect of annealing below $T_{\rm g}$ on the kinetics and spatial characteristics of nucleation, and with the assistance of preliminary calorimetric and light-scattering studies, it proved possible to determine thermal histories which would produce ordered distributions of microscopic ice crystals in our system. The conditions are critical, variations in choice of annealing temperature >1 °C not being allowed. Spectra showing the peak in Q described below were finally obtained using a nucleation temperature of 139 K (compare with $T_{\rm g} = 142$ K) for a period of 48 h, followed by observation at 140–142 K during which the nuclei which formed at the lower temperature grew to observable dimensions.

Following the annealing period, the sample still at 139 K was placed in the cold neutron beam of the D11 (low angle scatter-

ing) instrument of the ILL HFR (Grenoble). The wavelength of the study ($\lambda = 9$ Å) and the position of the multidetector (10 m behind the sample) were chosen so as to detect the correlations in the spatial distributions of the nuclei centres. With these conditions we obtained a range of scattered neutron wave vectors $2 \times 10^{-3} < Q < 3 \times 10^{-2}$ Å⁻¹. The counting time, 20 min, was a compromise based on the need to acquire reasonable statistics, while still following the time development of the system at a rate compatible with total allotted beam time.

At 139 K the sample gave only a very weak, featureless and time-independent scattered signal. This remained true while the temperature was raised slowly to 140.4 K. At this temperature, a statistically significant increase in scattering was observed, and the temperature increase was halted to permit isothermal observation of the sample time evolution (see Fig. 1). The scattered intensity which developed after 4 h is shown in Fig. 2a, and is notable for the intensity maximum at $Q_m = 0.9 \times 10^{-2} \, \text{Å}^{-1}$. This feature indicates some spatial organization of scattering centres, with a mean distance of separation of 700 Å.

After 6 h, the evolution effectively ceased, and to accelerate the development the temperature was raised (see Fig. 1). An increase in intensity and loss of peak definition was observed as the temperature rose to 143 K but thereafter an unexpected decrease in intensity occurred and continued until the signal virtually disappeared at 149 K (see Fig. 2b). The signal then reappeared, with a suggestion of a maximum in Q at the same value as before, and grew rapidly. This second increase was followed isothermally at 151 K (see Fig. 1) for 2 h. According to separate observations the sample, up to this point, remains optically transparent. Finally, observations were made during continuous temperature increase to T > 153 K, during which the sample becomes optically opaque, implying the presence of many large particles produced by ripening in the more diffusive conditions. Visible light scattering in the presence of a maximum in Q was also observable in microcrystallized cordierite glasses in the case where $\kappa_{\text{max}} < 1.5 \times 10^{-2} \text{ Å}^{-1}$ (ref. 7).

The observation of a maximum in the scattered intensity spectrum following annealing treatments similar to those used previously⁵ for silicate systems suggests that the ordering of crystallite centres has a common origin. The origin has been discussed elsewhere⁶ in terms of stabilization of crystallization centres initiated in highly metastable conditions in which the nucleation probability is high (because the critical nucleus radius is very small) and the diffusion length is small. The latter condition allows particles to grow independently of one another despite small separations if they lie beyond the region of steep concentration gradient established around each growing particle. New nucleation in the region of influence of each established

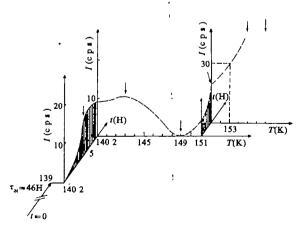

Fig. 1 Time-temperature-scattered neutron intensity schematic for this experiment. Note particularly the long annealing time at 139 K, the gradual development of scattered intensity with time at 140.2 K and the relatively sudden loss of intensity in the range 143-149 K. Short down-pointing arrows indicate conditions for the spectra shown in Fig. 2.

particle quickly becomes improbable in comparison with further growth of the established particle. Thus a preferred distance of separation, which is smaller the lower the temperature of nucleation, becomes established, and resists dissipation during the subsequent temperature increase to the value chosen for observation.

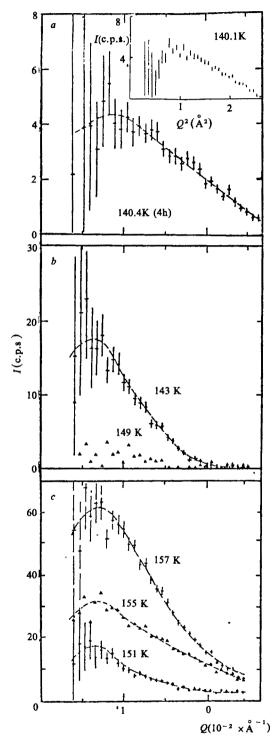

Fig. 2 Scattered neutron intensity in c.p.s. as a function of Q^2 at different stages of the experiment. a, After 4 h of development of 140.2 K. b, During temperature change in the range 143-149 K showing disappearance of signal. c, Development of signal with temperature increase between 151 K and 157 K. Note the maximum in I at $Q^2 \approx 0.9 \times 10^{-2} \text{ Å}^2$ in 140.4 K spectrum which persists throughout the experiment, with some movement to lower Q^2 values at higher temperatures. The same feature was seen better resolved (see insert to a) in an earlier exploratory experiment, for which the time-temperature history in the annealing range was less simple.

Considering the mean separation of crystallites of 700 Å, we observe that the nucleation density at 139 K must be at least 2.500 centres per um³—so high that the homogeneous nature of the nucleation phenomenon under study cannot be doubted. A Guinier plot of the high Q side of the peak yields an average crystallite size for the small particles, after initial development at 140.4 K, of ~100 Å. We can confirm approximately the size of particles which must be present by dividing the total ice volume which would form at complete desaturation (determined from the metastable extension of the ice saturation line in the phase diagram)4 by the number of scattering centres in the sample volume containing the precipitated ice. This calculation yields a maximum particle radius of 220 Å. Because our observation is made early during the desaturation process, an average radius of 100 Å seems reasonable.

The loss of scattering intensity at intermediate temperatures at first suggested that the initial scattering might have been due to a liquid-liquid phase separation which, as in the case of lithium disilicate⁷, produces conditions favourable for crystal nucleation. The new scattering centres which form in these conditions at a temperature above 149 K should produce a SANS spectrum unrelated to the initial pattern produced by the phase separation. That the renewed scattering pattern in the present case apparently retained the same maximum in Q as the initial scattering pattern suggests a more mundane explanation.

Neutron diffraction⁷ and calorimetric studies⁸ have now shown that the SANS phenomena observed result from a continuous development of microcrystals for T>140 K. This suggests that the peculiar variation in the scattered intensity for 143 K < T < 149 K (Fig. 1) probably originates in the relative variations in density and molar scattering power of the precipitated ice and the residual solution, which we can only assess approximately.

Combining data for the various isotopes, we find the scattering cross-section per mole of solution decreases rapidly with increasing concentration of LiCl. If, due to its large molar volume, the scattering power of ice initially formed from the supersaturated solution is weaker than that of the initial solution then, as the ice precipitates and residual solution concentrates, the contrast must pass through zero, giving a scattered intensity minimum. The low temperature density data for LiCl+D₂O solutions and D₂O ice necessary to confirm this hypothesis are not available, but extrapolations of LiCl+H₂O solution data, available down to -60 °C (ref. 9), show the postulated crossover is entirely possible. The explanation is also consistent with the relatively weak scattering observed at all temperatures.

Finally, the type of measurement described here provides a valuable basis for studies of other physical properties which, while sometimes more sensitive to the formation of the crystallizing phase8, contain no direct information on its size or distribution. These experiments and initial studies carried out at the eutectic composition, have produced no evidence in favour of a liquid-liquid phase separation occurring near T_{s} , either at the eutectic composition 10 or below 11

Setting of gabbroic dykelets in an ophiolitic complex by hydraulic fracturing

I. Reuber, H. Whitechurch & J. M. Caron

Institut de Géologie, 1 rue Blessig, 67084 Strasbourg Cedex, France

Gabbroic dykelets cutting peridotitic tectonites are generally interpreted as the product of *in situ* partial melting, or as the path of upward moving magma. However, we report here that their structure strongly suggests emplacement by hydraulic fracturing, and their bulk and mineral chemistry indicate that they were highly differentiated liquids issued from the overlying magma chamber. They cannot be the feeding channels of the magma chamber, which contains the primitive liquids produced by partial melting of the upper mantle.

Within ophiolitic complexes, several types of dykelet (usually 1-5 cm wide, exceptionally up to 50 cm) can be observed in both the tectonite and the cumulate sequences. They are called dykelets to distinguish them from the isolated diabase dykes¹, which are ~2 m wide and cut throughout the ophiolitic sequence. Because the small dykelets have previously been interpreted as the feeding channels of the cumulate magma chamber¹²², in looking for the path and mechanism of feeding for the chamber we concentrated our investigations on the Antalya ophiolite complex (Fig. 1), which is particularly rich in internal structures related to ridge activity³.⁴.

This ophiolite consists of two well-exposed complexes (Fig. 1), the tectonic harzburgite massif of Adrasan in the south, and the massif of Cirali/Tekirova ~15 km farther north, consisting of harzburgitic tectonites and magmatic ultrabasic and basic cumulates. The coarse-grained texture ('S1') of the tectonites is due to high temperature, high-pressure, low-creep stress plastic flow below an oceanic ridge. However, in Adrasan and at the south end of the Cirali/Tekirova massif, shear zones with a porphyroclastic texture ('S2') are evidence of a low temperature, low lithostatic pressure, high creep stress deformation, obviously linked to intra-oceanic thrusting before obduction⁵⁻⁸.

A group of leucocratic gabbro dykelets can be observed among all dykelets occurring either in the tectonites (commonly deformed dunite and pyroxenite veinlets) or in the cumulates (nondeformed pyroxenite and gabbro dykelets) (I.R., in preparation). They never exceed 1% of the total rock, even in areas where they appear to be abundant, and may total $\sim 0.05\%$ of the massif. Their abundance in the tectonites decreases rapidly downwards in the upper 500 m.

These gabbroic dykelets neatly cross-cut all structures due to and affected by the plastic flow below the ridge, as well as the magmatic structures in the cumulates. Their mineralogy and chemistry are similar in both parts of the ophiolite, and quite different from those of the other dykelets. In fact, their bulk rock as well as their mineral chemistry (bulk rock chemistry analyses are representative of the total dykelet, as the sharp contact between dykelet and host rock permitted easy separation of the two, Figs 2, 3) correspond to those of evolved residual magmatic liquids, similar to the liquids which crystallized in residual pockets (Fig. 4e) in the upper part of the cumulate sequence. As Fig. 2 shows, there is a marked decrease in the MgO content and an increase in the Al₂O₃ content for the same SiO₂ and CaO contents, compared with those of the host plagioclase-wherlite or host gabbros of the cumulate sequence. The most differentiated dykelets are those found within the harzburgitic tectonites. This same trend occurs in the chemistry of clinopyroxenes and orthopyroxenes (Fig. 3), which show an enrichment in Fe content. Again, this enrichment is most important for the dykelets in the tectonites.

Thus, the leucocratic gabbro dykelets could not be the feeding channels of the overlying cumulate magma chamber. Their chemistry does not correspond to that of liquids produced by upper mantle partial fusion, nor to a possibly picritic parental magma, from which a thick layer of ultramafic cumulates could have crystallized, but it does correspond to the composition of residual liquids developed in the overlying gabbroic cumulates. Actually, the composition of MORB primitive liquids 9-12 corresponds to a mean value for the cumulates of Antalya (except for CaO values, which are quite dispersed anyway). However, the composition of the gabbro dykelets is considerably more evolved. Neither do they resemble that of the Cyprus upper pillow lavas¹³, believed to represent off-axis magmas¹⁴. When the Omanian gabbro dykelets, partly considered to be off-axis magma⁸, are replotted, we find that they can be divided into two groups: Al₂O₃-poor, MgO-rich dykelets, which correspond to little fractionated cumulate composition, and Al₂O₃-rich, MgOpoor dykelets, which might be the nondeformed ones; their

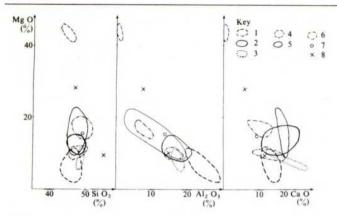

Fig. 2 Harker diagrams of bulk rock chemistry (27 analyses) showing that the differentiation from cumulate host rock—residual pockets and gabbro dykelets within cumulates—gabbro dykelets within tectonites mainly consists of a decrease in MgO and an increase in Al₂O₃. 1, Gabbro dykelets in the tectonites; 2, gabbro dykelets in the cumulates; 3, residual pockets in the cumulates; 4, tectonite host rock; 5, cumulate host rock; 6, gabbro dykelets from Oman⁸; 7, MORB primitive liquid (mean of values from refs 9-12); 8, Cyprus upper pillow lavas¹³.

emplacement might be explained in the same way as for Antalya.

Thus, if the leucocratic gabbro dykelets within the harzburgitic tectonites are residual liquids coming from the overlying magma chamber, what is the mechanism of downward injection? Their geometry, although varying from one outcrop to another, strongly suggests their setting by hydraulic fracturing (see ref. 2): (1) The end of the dykelets may be marked by small. branching and zigzagging dykelets, matching the images found by Beach 15 for experimental hydraulic fractures. (2) At the scale of a single gabbro dykelet, anastomosing dykelets and magmatic brecciation are frequent at the dyke walls (Fig. 4a). (3) Such brecciation may result in interconnected anastomosing dykelets (Fig. 4b), and even in large brecciated areas, occurring preferentially near the contact between tectonites and cumulates. As the liquid is more abundant, they are better developed on the cumulate side (Fig. 4c). (4) Straight, long, parallel dykelets have also been set by hydraulic fracturing (see below) (Fig. 4d).

Hydraulic fracturing probably occurred after the interstitial liquid had been expelled from between the cumulus minerals, since traces of such interstitial minerals are rarely observed in

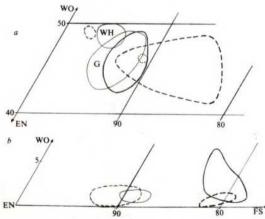

Fig. 3 Plot of clinopyroxene (a) (40 analyses) and orthopyroxene (b) (22 analyses) composition in a greatly enlarged En-Fs-Wo triangle, showing two groups neatly separated for the orthopyroxene: host rock orthopyroxene at En₉₀, and orthopyroxene of the dykelets clearly richer in Fe with En₈₀. With corresponding values the clinopyroxene show a continuous enrichment in Fe from tectonite host rock, via cumulate host rock (WH = wherlite, G = gabbro) and gabbro dykelets in the cumulates, to gabbro dykelets in the tectonites. Key as for Fig. 2.

the Antalyan cumulates. This interstitial liquid would be gathered in residual pockets, from which extending dykelets are frequently observed (Fig. 4e), indicating that liquid overpressure within the pockets provoked fracturing. Relative abundance of liquid (locally exceeding 20% of the total rock) facilitates brecciation, particularly affecting the less permeable rocks, such as the dunites at the contact between tectonites and cumulates.

The variable geometry of these gabbroic dykelets could be explained by the interference between stresses of different origin², that is, fluid pressure (p), deviatoric stress $(\Delta\sigma)$ and confining lithostatic pressure. Cracks created by hydraulic fracturing, and thus directly dependent on the fluid pressure, will be found in conditions intermediate between the following cases: (1) Deviatoric stress is zero: fluid pressure need only overcome the confining pressure and the rock coherence. As both pressures are isotropic, cracks should be created equally in all directions, unless guided by rock anisotropy, and the result will be anastomosing veins. (2) Deviatoric stress is medium: cracks will be guided by the anisotropic stress field. As the confining pressure is weak, tensile failure parallel to $\sigma_1 \times \sigma_2$ plane is

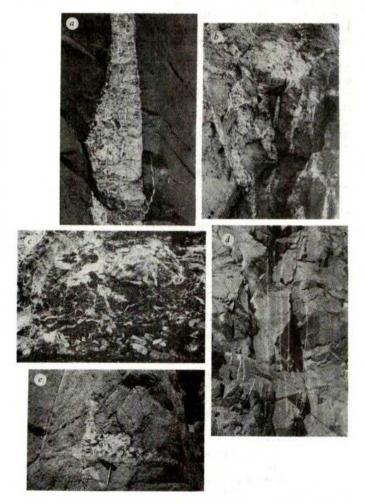

Fig. 4 a, Leucocratic gabbro dyklet (10–25 cm wide) within the tectonites of Adrasan. Foliation S2 is parallel to the dykelet and especially strong in the mylonitic shear zones. Fig. 5 Schematic model of a mid-oceanic ridge to show that the emplacement of the leucocratic gabbro dykelets by hydraulic fracturing takes place at a late stage in the evolution of the cumulate magma chamber.

possible, if the fluid pressure p yields $p > 3\sigma_2 - \sigma_1 + T_0$ (where T_0 = tensile strength¹⁶). Dykelets resulting from such tensile fracturing initiated by fluid pressure will be long, straight, and parallel to one another. (3) Deviatoric stress is high: cracks will still be guided by the anisotropic stress field, but instead of tensile fractures, shear fractures will develop. Such fractures are oblique on the $\sigma_1 \times \sigma_2$ plane, short and irregular, with a characteristic en echelon arrangement. With increasing fluid pressure the propagation speed of such cracks, and its deviation from the theoretical shear fracture direction, will increase¹⁷. The resulting more irregular fractures and especially their en echelon arrangement have also been observed in a lesser amount. They appear to be anterior to the anastomosing and then to the straight dykelets.

The stress conditions in an oceanic spreading centre clearly depend on the locality below the ridge. Thus, a given rock assemblage will be submitted to varying stress regimes as it travels away from the ridge centre. Hydraulic fracturing, although occurring at a late stage with respect to the cumulate magma chamber's evolution, must be active over a longer span of time, as several generations of dykelets produced by hydraulic fracturing, or dykelets cutting magmatic breccias are observed. At one outcrop the younger the dykelet, the more differentiated its chemistry. In general the succession of the different vein geometries points to high deviatoric stress conditions nearest to the spreading centre, passing via isotropic conditions to tensile stress away from the ridge.

In conclusion, the leucocratic gabbro dykelets cutting the tectonite and cumulate sequences of the Antalyan ophiolitic complex, constitute the latest generations of all the dykelets observed (except for the much later injected diabase dykes). They have been formed by hydraulic fracturing in variable stress conditions. They are not the feeding channels of the overlying magma chamber, which must be looked for among the other dykelets (I.R., in preparation), but their very differentiated chemistry indicates that they have originated from the overlying cumulates. They have been injected at a late stage of the cumulate magma chamber evolution in all directions in the cumulates, and downwards into the tectonites (see Fig. 5).

We thank A. Nicolas, R. G. Coleman and T. Juteau for helpful remarks and discussions. Financial support was provided by ATP 'Geodynamique' from the French INAG.

Methane production and simultaneous sulphate reduction in anoxic, salt marsh sediments

Ronald S. Oremland, Lorraine M. Marsh & Sandra Polcin

US Geological Survey, 345 Middlefield Road, Menlo Park, California 94025, USA

It has been generally believed that sulphate reduction precludes methane generation during diagenesis of anoxic sediments^{1,2} Because most biogenic methane formed in nature is thought to derive either from acetate cleavage or by hydrogen reduction of carbon dioxide³⁻⁶, the removal of these compounds by the energetically more efficient sulphate-reducing bacteria can impose a substrate limitation on methanogenic bacteria? However, two known species of methanogens, Methanosarcina barkeri and Methanococcus mazei, can grow on and produce methane from methanol and methylated amines¹⁰⁻¹³. In addition, these compounds stimulate methane production by bacterial enrichments from the rumen 11,14 and aquatic muds Methanol can enter anaerobic food webs through bacterial degradation of lignins¹⁵ or pectin¹⁶, and methylated amines can be produced either from decomposition of substances like choline, creatine and betaine 13,14 or by bacterial reduction of trimethylamine oxide¹⁷, a common metabolite and excretory product of marine animals. However, the relative importance of methanol and methylated amines as precursors of methane in sediments has not been previously examined. We now report that methanol and trimethylamine are important substrates for methanogenic bacteria in salt marsh sediments and that these compounds may account for the bulk of methane produced therein. Furthermore, because these compounds do not stimulate sulphate reduction, methanogenesis and sulphate reduction can operate concurrently in sulphate-containing anoxic sediments.

Sediments were taken from the upper 15 cm of a salt marsh located in San Francisco Bay at Palo Alto, California. The black, highly reduced sediments contained methane (~8 ml per 1 wet sediment; T. Vogel et al., unpublished data) and smelled strongly of hydrogen sulphide. The sediments also contained abundant plant material (such as roots, rhizomes, stems and leaves) of Spartina foliosa. Glass jars were filled completely with sediment (to exclude air) sealed and transported back to the laboratory. Experiments began within 1 h of sample collection. Sediments were homogenized anaerobically 18° with San Francisco Bay water (salinity $\simeq 20\%$; sulphate $\simeq 18$ mM) to pro-

Table 1 Effect of methanol and sulphate on formation of methane and sulphide by sediment slurries incubated for 6 days

Conditions	CH4 (µmol per flask)	S ⁻² (µmol per flask)
Methanol+sulphate	192 ± 28	126 ± 13
Methanol - sulphate	162 ± 16	104 ± 22
No amendments + sulphate	0.90 ± 0.05	111 ± 22

Results represent the mean ± 1 s.d. of three flasks. Sulphide was measured by cadmium analysis of acidified sediments on an initial levels were $\sim 9~\mu mol~S^{-2}$ per flask. The artificial media contained (g l⁻¹)· NaCl, 12; MgCl₂·6H₃O, 55; CaCl₂·2H₂O, 0.75; KCl, 0.38; NaBr, 0.04; NaHCO₃, 0.25; Na₂SO₄ or NaCl, 2.8; trace element solution on the sediment homogenate (1·1, sediment: media) Sulphide produced in the sulphate-free flasks was probably from organic sources and reduction of interstitial sulphate ions that were originally present in the sediment sample. Sulphide production was stimulated by amendment with either accetate or H₂ (S.P. and R.S.O., in preparation). Hydrogen also stimulated CH₄ production by these sediments. After 5 days, H₂-incubated slurries produced more CH₄ (8 2 \pm 5.3 μ mol per flask) than N₂-incubated slurries (0.098 \pm 0.007 μ mol per flask). However, much more H₂ was consumed by the slurries (506 \pm 61 μ mol than required for methanogenesis, because of H₂ oxidation by sulphate-reducing bacteria?

duce a dense homogenate which was dispensed into Erlenmeyer flasks and sealed under N2. In some experiments, the homogenate was further diluted with bay water to yield a slurry¹⁸. To test the influence of sulphate on methanogenesis from methanol or trimethylamine, dilute slurries were also prepared by homogenizing sediment in a sulphate-free artificial media and dispensing the homogenate into flasks containing more of the same media either amended with or lacking sulphate (Table 1). Additions were made to selected flasks, where indicated, of homogenized Spartina material, 14C-methanol and methanol. 2-bromoethanesulphonic acid (BES) was added to certain flasks to inhibit methanogenic bacteria 18,19. BES functions as a specific inhibitor of methanogens because the compound is a structural analogue of coenzyme M (2-mercaptoethanesulphonic acid)¹⁹; coenzyme M occurs only in methanogenic bacteria²⁰. All flasks were incubated in the dark at 19 °C with constant rotary shaking (200 r.p.m.).

Incubation of sediment homogenates in the presence of BES inhibited methane formation and caused increases in the pool sizes of methanol and trimethylamine with time (Fig. 1). In contrast, uninhibited flasks produced methane and had lower, fluctuating pool sizes of both methanol and trimethylamine. Hydrogen did not accumulate in appreciable quantities (~100–200 nmol per flask; day 2) in either the BES or the uninhibited flasks, and the gas was not detected by day 3 in any of the flasks. In a second experiment, addition of ¹⁴C-methanol to freshly prepared sediment homogenates resulted in the immediate, linear production of ¹⁴CH₄ and production of both ¹⁴CH₄ and CH₄ were inhibited by BES (Fig. 2).

In experiments with dilute sediment slurries, methanolamended flasks (500 μ mol per flask) produced methane and production levelled off after 5 days incubation. Levels of methane formed in replicate flasks (310 and 340 μ mol per flask) accounted for an 83–91% conversion of the methanol, based on the reaction:

$4CH₃OH \rightarrow 3CH₄ + CO₂ + 2H₂O$

Flasks incubated with methanol plus BES (3.5 mM) did not produce significant amounts of methane ($<0.5 \,\mu$ mol CH₄ per flask after 2 weeks incubation). Methane formation (from methanol) by sediment slurries incubated in artificial media was not influenced by the presence of sulphate. The rates and extent of methane formation with time were identical for flasks which either contained or lacked sulphate ions (20 mM) and the levels of methane achieved at the end of the experiment (6 days) were comparable (Table 1). Amendment of these slurries with methanol greatly stimulated methanogenesis but did not stimulate sulphate reduction (as measured by S⁻²; Table 1). We have obtained similar results for trimethylamine using slurries pre-

pared from nearby intertidal mudflat sediments (S.P. and R.S.O. in preparation).

The accumulation of trimethylamine and methanol in BESinhibited homogenates (Fig. 1) indicates that these compounds are usually present in these sediments, but are continuously removed and converted to methane by methanogenic bacteria. In addition, no lag of ¹⁴CH₂ production occurred on addition of ¹⁴C-methanol to sediment homogenates (Fig. 2). Because production of ¹⁴CH₄ was immediate and linear, the methanogens present in the sediments were substrate adapted to methanol and presumably, trimethylamine (14C-trimethylamine was not tested). Furthermore, because 4 mol of trimethylamine can produce 9 mol of methane¹³, the large pool sizes of trimethylamine (Fig. 1b) at day 2 (~57 µmol per flask, corresponding to $\sim 570 \, \mu \text{mol l}^{-1}$) could account for all the methane produced (~37 µmol CH₄ per flask at day 3) with 10% coming from methanol. Hydrogen was not an important energy source for methanogens because there was no appreciable accumulation of this gas either in the presence or absence of BES. Disappearance of hydrogen by day 3 therefore, was due to removal by sulphate reducers and other anaerobic bacteria⁷

As methanol and trimethylamine stimulate methanogenesis, but not sulphate reduction, the two processes can operate simultaneously and independently within anoxic sediments containing these compounds and sulphate ions. It is significant that other workers have observed a rapid conversion of ¹⁴C-methylamine to ¹⁴C-methane in sulphate-containing marine sediments (M. Winfrey and D. Ward, personal communication). Thus, in sediment pore waters containing relatively high concentrations of sulphate, sulphate reduction proceeds at the expense of short chain fatty acids and hydrogen⁹ while methanogenesis can occur simultaneously through metabolism of non-competitive substrates, such as methanol and methylated amines. As sulphate becomes depleted from sediment pore waters, short chain fatty acids and hydrogen can enter

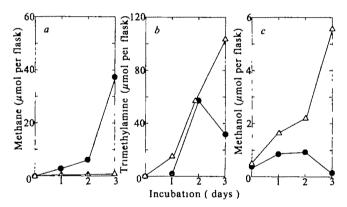

Fig. 1 Levels of methane (a), trimethylamine (b) and methanol (c) in uninhibited flasks (●) and flasks containing 0.7 g BES (△) Flasks (total volume, 138 ml) contained 80 ml sediment homogenate (1.1, sediment bay water), 10 ml bay water and 20 ml homogenized S. foliosa materials (1.1 with bay water) A set of eight flasks (four uninhibited, four + BES) were incubated with constant shaking (dark, 19 °C) Two flasks were used daily for methanol and trimethylamine determinations. Homogenate was centrifuged (4°C) and supernatant distilled (90-100°C) Fractions of distillate (100- $500\,\mu l)$ were collected and analysed by flame ionization gas chromatography 18 using 5 μl injections and a 183×0 64 cm stainless-steel Porapak Q column (110 °C) Compounds were identified by retention time. Per cent recoveries of methanol (75%) and trimethylamine (46%) were obtained by distillation of standard solutions, however, distillation efficiencies were not applied to pool size estimates for the purpose of being conservative. The presence of trimethylamine in the distillate was confirmed by mass spectrometry (Accurex Co) One µl of sample was purged onto a Tekman LSC 2 and thermally absorbed onto 0 5% carbopak 1500 carbopak column. The column was ramped from 60 to 200 °C and effluent detected on a Finnegan 1020 gas chromatograph-mass spectrometer scanning 41-275 AMU every 2 s The samples had AMU peaks at 59 (trimethylamine) and were identical with prepared standards. Methanol also accumulated in flasks that contained only homogenized sediments (no added plant materials) After 7 days incubation, 5.5 and 332 nmol CH₃OH were recovered from uninhibited and BES flasks, respectively (trimethylamine was not searched for) The flasks had produced 3,200 nmol CH₄ (unmhibited) and 300 nmol CH₄ (BES) after 1 week

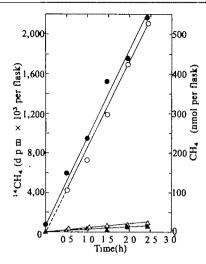

Fig. 2 Formation of CH₄ and ¹⁴CH₄ by homogenates amended with ¹⁴C-methanol (12.5 μCi per flask; 0.28 μmol per flask, ICN Co, initial specific activity 45 mCi mmol⁻¹) Unhibited flasks: ¹⁴CH₄, Φ; CH₄, O. Flasks inhibited with BES (1 g). ¹⁴CH₄, Δ, CH₄, Δ Flasks (total volume, 263 ml) contained 145 ml of sediment homogenate (1.1 with bay water), 25 ml bay water and 65 ml of homogenized S foliosa materials (1.1 with bay water) Flasks were incubated in the dark (20°C) with constant rotary shaking (200 r.p.m.) ¹⁴CH₄ and ¹⁴CO₂ were determined by gas chromatography—gas proportional counting procedures²⁷ and CH₄ by gas chromatography¹⁸

methanogenic pathways. Therefore, the ecological niche occupied by methanogens seems broader than previously predicted^{1,2}. As most studies on sediment methanogenesis used ¹⁴Cacetate or ¹⁴C-bicarbonate as precursors of methane^{6,21}, results can be misleading with regard to zones of methane production and may also underestimate carbon budgets. Future studies should be directed at determining the contribution methanol and methylated amines make to the methane formed in various aquatic sediments. Because carbon isotope enrichment factors are significantly greater in methanol-grown methanogens (~70%)^{23,26} than in hydrogen plus carbon dioxide-grown cells (~40%)²², such information would be of importance for the interpretation of carbon isotopic fractionations of methane during methanogenesis in anoxic sediments.

We thank R. Gunsalus, D. Ward and M. Winfrey for helpful discussions, K. Kvenvolden, R. Smith and W. Balch for discussions and manuscript review, and G. Nicoll for the mass spectrometry work. Mention of brand name products does not constitute an endorsement by the US Geological Survey.

Sulphate and sulphate reduction in early Precambrian oceans

E. M. Cameron

Geological Survey of Canada, Ottawa, Ontario, Canada KIA OE8

Sulphate reduction generally causes isotopic fractionation of sulphur¹. Modern sedimentary sulphide is largely produced by biogenic reduction of sulphate and is typically enriched in ³²S (ref. 2). This is balanced by excess ³⁴S in the oceanic sulphate reservoir and evaporites3. High-temperature, inorganic reduction of sulphate may also cause fractionation^{4,5}. Since the work of Ault and Kulp⁶, there has been interest in finding the beginnings of sulphate reduction in the sedimentary record. This is important for several reasons. First, sulphate-respiring bacteria are a milestone of evolution^{7,8}. Second, it established the exogenic sulphur cycle in an essentially modern form. This, with the interconnected oxygen and carbon cycles, regulates the composition of atmosphere and oceans⁹⁻¹¹. Third, widespread evidence of sulphate reduction in rocks of a given age and younger indicates that sulphate was established as a major constituent of seawater. In addition to identifying a stage in the evolution of an oxygenated environment¹⁰, this has important metallogenic implications. Schidlowski⁸ has recently concluded that dissimilatory reduction commenced at 2.800-3,100 Myr in an Archaean ocean that had relatively high concentrations of sulphate. I review here the published data and present additional sulphur isotope analyses obtained from the early Precambrian of South Africa. These results indicate that sulphate was a minor component of Archaean and early Proterozoic ocean water, probably <0.001 mol l⁻¹. The concentration had increased by ~2,350 Myr to levels allowing significant biogenic and inorganic fractionation and the partitioning of ³²S/³⁴S in the exogene cycle.

Information provided by Precambrian evaporitic sediments is limited. The oldest Proterozoic evaporites for which data are published have maximum ages of only 1,300 Myr. These have 834S values of up to 30% (refs 12,13), indicating that sulphate reduction was well established at that time. Stratiform barites found in >3,200 Myr rocks on several continents have δ^{34} S of ~0\% indicating no significant isotopic partitioning in the oceans of that time.

Figure 1 gives the means and standard deviations of δ^{34} S for groups of sedimentary sulphide of Archaean (>2,500 Myr) and Aphebian (2,500-1,800 Myr) age. Where geological information permits, the latter have been subdivided into 'Aphebian 1' (>2,300 Myr) and 'Aphebian 2' (≥2,300 Myr). Data have been excluded where the rocks may have been affected by metasomatism. Care must be taken in interpreting the statistical data, as the sample collections vary greatly in size and in stratigraphical and geographical extent.

Several generalized fields have been outlined in Fig. 1, related to the genesis of the sulphides. Magmatic sulphides have δ^{34} S values close to 0% and low variance. Groups with more positive δ^{34} S values, but also low variance, have been identified as the product of partial reduction of ocean sulphate at high temperature, for example, the Red Sea¹⁴ and in Homestake Mine sediments¹⁵. However, depending on the degree of fractionation⁵ and δ^{34} S of ocean sulphate, this field can presumably extend into or across the 'magmatic' field.

Sample groups having distinctly negative $\delta^{34}S$ values and moderate to high variance are attributed to biogenic sulphate reduction in systems open to exchange with ocean sulphate¹⁶. Groups enriched in ³⁴S and with moderate to high variance have been imputed to closed-system sulphate reduction 17,18 that presumably may be either inorganic or biogenic.

All of the Archaean and 'Aphebian 1' groups fall into a restricted range close to 0% $\delta^{34}S$ and low variance, characteristic of magmatic sulphur. The possible exceptions are the 2,750 Myr Woman River and Michipicoten iron formations. The greater variation found in these two groups has been ascribed to biological reduction of low concentrations of sulphate within a restricted basin¹⁹. This interpretation has not been universally accepted²⁰⁻²². As the metals of the iron formations were almost certainly derived from thermal springs²³, fractionation of sulphur at high temperature may have been involved. Indeed, sulphide formed by high-temperature reduction will tend to show the greatest variation in $\delta^{34}S$ at low sulphate concentrations, that is $\Sigma SO_4^2 = \Sigma H_2S$, because of the sensitivity of fractionation to solution chemistry near the SO_4^2 / H_2S boundary⁵.

While the evidence for bacterial reduction in the Archaean is debatable, there is little doubt that during this time there was no quantitatively important partitioning of ³²S/³⁴S in the exogene cycle, as shown by the data from five continents summarized in Fig. 1 that have means clustered near 0%. Also, on the basis of the limited published evidence, this condition persisted into 'Aphebian 1' time.

Partitioning was established at the time of deposition of the Karelian schists²⁴ at ~2,200 Myr. Also, the Outokumpu deposit, a submarine exhalative massive sulphide body within the Karelian, dated at 2,250 Myr (ref. 25), shows a wide range of δ^{34} S from -19.2% to 5.8% (ref. 26). Unfortunately, some of the most comprehensive data on sedimentary sulphides of Aphebian age come from strata whose age is known only within broad limits, that is at the Homestake Mine¹⁵ and the Pine Creek geosyncline²⁷. The enrichment of ³⁴S in many of the early Precambrian units measured to date is intriguing and requires to be balanced by excess ³²S elsewhere²⁸.

To provide further data on sulphur isotope fractionation, I have sampled shaly sediments in the Republic of South Africa, representative of the period 3,300–2,000 Myr. This country contains some of the most complete and best exposed early Precambrian successions. Moreover, cratonic conditions were established at a relatively early date here^{29,30}, giving rise to Archaean sediments of different facies from the more typical 'greenstone belt' type. This is important, as the volcanogenic sulphide which dominates the greenstone belts²⁸ may have obscured any biogenic contribution.

Because sulphide is often difficult to separate physically from carbonaceous shale, the sulphur isotopic data were mainly obtained by burning powdered shale in O_2 at 1,300 °C to produce SO_2 . Analyses of pyrite and/or pyrrhotite separated from 20 of these samples give similar $\delta^{34}S$ values to the total

burn. The organic carbon and the sulphur contents are quite variable for the samples from the Swaziland and Transvaal Supergroups, with values to 5.5% C and 3.2% S for the former and 9.6% C and 4.5% S for the latter. The West Rand Group samples have lower values for carbon, ranging to 0.4% C and 4.2% S.

Deposition of the Transvaal sediments took place mainly in a shallow, marine environment³¹, while the upper part of the Onverwacht was laid down in shallow water, in part possibly evaporitic³². The depositional site of Witswatersrand strata has been enigmatic, either a shallow inland sea, or a lake³³. But Watchorn³⁴ found tidal features in the West Rand Group and both fluvial and shallow water marine facies. Many of the West Rand shales are low grade iron formations, which has been taken as evidence of marine origin³⁰.

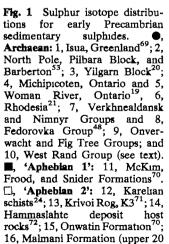

The results (Fig. 2) show δ^{34} S values close to 0% for all

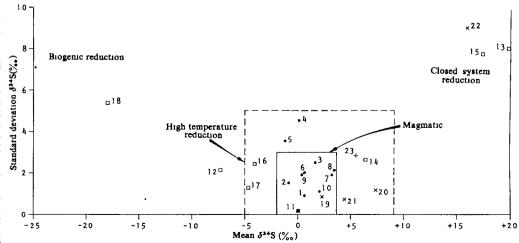

The results (Fig. 2) show δ^{34} S values close to 0% for all samples up to and including the lowermost part of the Malmani Subgroup. This reflects a magmatic source of the sulphide, either directly from volcanic exhalations, or from detrital sulphide that survived weathering in an O_2 -poor atmosphere. Above this, the character of the isotopic distribution is entirely different, with mainly negative numbers. I suggest that the sulphides from the shales above the isotopic transition were derived from reduction of sulphate, with both biogenic and inorganic processes probably being involved.

Sulphide from carbonaceous shale of the Timeball Hill Formation is undoubtably biogenic with whole rock values to -30.6% (pyrite from the same sample measured -30.5%). Two sections were sampled, one being the basal 30 m of the formation in a drill core at Mafefe, northern Transvaal and the other the basal 10 m from a core at Fochville, 400 km distant. The lowest ³⁴S values are from the most sulphidic shales.

Two 20-m sections of pyritic shale from the basal Malips Member of the Penge Iron Formation were taken: one from Mafefe, the other at Penge, 45 km away. They show very similar δ^{34} S values with means of -4.8% and -4.9% respectively and a low standard deviation for all samples of 1.3%. These absolute values, plus the uniformity of the data, suggest derivation by high-temperature reduction, then thorough mixing before or after exhalation.

The Malmani samples are from carbonaceous shale interbeds in this carbonate unit and are taken from a 1,200-m section near Fochville, plus two samples from Mafefe immediately below the Penge Formation. In part, these data may be interpreted (Fig. 2) as hydrothermal sulphide, similar to the Malips Member. The Malmani is a chemical precursor of the great iron deposits of the Penge and Kuruman Formations, with cycles of iron enrichment in the carbonate³⁵. However, caution

samples, Fig. 2), 17 Penge Formation; 18, Timeball Hill Formation (see text). ×, Aphebian undivided: 19, Cahill Formation²⁷; 20 Homestake Formation; 21, Poorman Formation and 22, Ellison Formation¹⁵. +, Modern: 23, Red Sea, hydrothermal (SU1 and SU2 zones)¹⁴. Additional geochronological data from ref. 73.

must be used in interpreting these data, as both upper intertidal and subtidal shales have been identified in the Malmani (ref. 36 and N. J. Beukes personal communication). Each shale type is likely to have a different isotopic distribution. The isotopic transition (Fig. 2) is placed between samples 45 and 77 m above the base of the Malmani. The samples above and below the transition, including those from the Black Reef, are similar, being carbonaceous to highly carbonaceous shales.

The Malmani is bracketed by age determinations of 2,640 Myr for the middle group of the Ventersdorp³⁷ and 2,240 Myr for the Ongeluk lavas of the Pretoria Group (D. Crampton, in ref. 38). Both of these horizons are separated from the Malmani by major unconformities. However, the base of the Malmani is probably closer in age to the Ongeluk than to the Ventersdorp. For this reason the isotopic change is estimated at ~2,350 Myr, a figure likely to be changed with more detailed geochronology.

The isotopic transition at $\sim 2,350$ Myr is indicative of one of two possible conditions, the first being an increase in the sulphate concentration of seawater to a level sufficient for reduction to cause significant isotopic fractionation. Harrison and Thode³⁹ showed that the fractionation by Desulphovibrio desulphuricans is sharply reduced at $< 0.001 \text{ mol}^{-1} \text{ SO}_4^{2-}$, equivalent to ~4% of the concentration in present seawater. For inorganic reduction over the temperature range 200-350 °C at neutral pH, fractionation is minimal when $\Sigma SO_4^{2-} < \Sigma H_2 S$ (ref. 5).

The second possible explanation is that sulphate-reducing bacteria evolved at ~2,350 Myr in a pre-existing, sulphate-rich ocean. This is less plausible if it is accepted that the Aphebian also marks the first significant appearance of sedimentary sulphide produced by high-temperature reduction of sulphate, for example, the Homestake Formation¹⁵ and the data given

here.

Further evidence of an evolutionary change from a lowsulphate Archaean ocean is the sulphur isotope composition of massive sulphide base metal deposits. Those of Proterozoic and younger age have mean δ^{34} S values that commonly differ significantly from 0% (refs 40,41), a fact which has been ascribed to derivation, in part at least, by reduction of seawater sulphate 40,42,43. Late Archaean (~2,700 Myr) massive sulphides have mean values close to 0% (ref. 41), although seawater also had a major role in their formation⁴⁴. Sulphate minerals are absent in these Archaean deposits^{45,46}, whereas they are relatively common in younger deposits.

Possibly contrary evidence is the occurrence of stratiform barite in the Archaean of southern Africa^{32,47-51}; in the Pilbara Block of western Australia⁵²⁻⁵⁴; in India⁵⁵; and in the USSR⁴⁸. Where reliable age determinations are available, it seems that these sulphates occur in older Archaean strata, that is

 $>3,200 \, \text{Myr}.$

Studies carried out on the little metamorphosed Pilbara and Barberton occurrences indicate a depositional environment unusual for the Archaean. That is, a rather extensive, tectonically stable shallow-water shelf with volcanic vents but little detritus⁵⁴. At least some sulphate was deposited in evaporitic conditions as gypsum, then replaced by silica and barite 53,54,56 Younger Archaean strata, such as that which dominates the Canadian Shield, lack barite⁵⁰ and shallow water environments of the type described above are rare.

The Pilbara and Barberton barites probably were deposited in restricted basins where sulphate produced, for example, by bacterial oxidation of sulphide⁴⁷, could increase to higher concentration than in the ocean. Mean δ^{34} S values of 3.6-3.8% for these barites⁵³ indicates that isotopic partitioning was not established in the early ocean. The model discussed below linking global tectonics with ocean sulphate content does not, however, preclude short-term increase in sulphate within Archaean oceans in response to any temporary decline in rates of plate formation.

The data presented here indicate that during Archaean time sulphate was a minor constituent of seawater, probably <0.001 mol l⁻¹, except within restricted basins. This condition

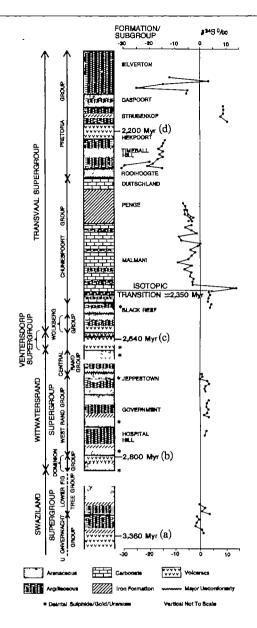

Fig. 2 Sulphur isotope results, early Precambrian argillaceous sediments, Republic of South Africa. Stratigraphical thicknesses not to scale. Isotopic data plotted in true stratigraphical order but not to represent a stratigraphical position within any given unit. Geochronological data: (a) ref. 74; (b) ref. 75; (c) ref. 37; (d) D. Crampton in ref. 38.

persisted into the Proterozoic, but by ~2,350 Myr, sulphate had reached a level sufficient for biogenic or inorganic reduction to cause significant isotopic fractionation and the partitioning of ³²S/³⁴S in the exogene cycle.

The change in the sulphate concentration of the ocean coincides with a suggested initial increase in the oxygen content of the atmosphere above the primitive level of $<(10^{-2}-10^{-6})$ PAL required for the deposition of placer uraninite⁵⁷. The isotopic transition (Fig. 2) occurs immediately above the youngest occurrence in South Africa of detrital sulphides and uraninite in the Black Reef^{58,59}. In the Huronian of Canada a change from strata hosting pyritic-uraniferous conglomerates to those with black (oxide) sands and red beds occur at ~2,300 Myr (ref. 60).

The transition, during the Lower Proterozoic, from an anoxic atmosphere to one with low levels of O₂ has been attributed to the filling of oceanic sinks for O_2 , notably Fe^{2+} derived from continental weathering ⁶¹⁻⁶⁴. It is curious that this transition and the increase in oceanic sulphate discussed here, approximately coincided with the greatest tectonic milestone in geological history: the change from a highly mobile Archaean crust to a Proterozoic regime of stable continental masses. Consideration must be given to alternative models, relating atmospheric and hydrospheric evolution to tectonic change.

The dominant mechanism for maintaining O₂ and SO₄² at low levels during the Archaean may have been a greater rate of exchange of reduced materials between the mantle and the ocean. Edmond et al.65 estimate the flux of SO₄ into modern submarine geothermal systems as equivalent to that entering the oceans from rivers. Moreover, major amounts of Fe2+ and Mn²⁺ are introduced into the oceans from the ridges.

As the driving force for the exchange between mantle and ocean is heat flow, one would expect this to be greater in the Archaean. Furthermore, there is reason to believe that the exchange was even greater in the Archaean than might be predicted from a linear relationship with the Earth's heat flow. Burke and Kidd⁶⁶ suggest that during this period a greater proportion of the Earth's heat was dissipated at ocean ridges. Bickle⁶⁷ calculated that plate formation was about six times greater at 2,800 Myr than at present, compared with a factor of about three for heat flow. The Archaean/Proterozoic boundary seems to mark a change from a regime of rapid plate formation to a slower one 68 that would, in turn, produce a lower rate of exchange between reduced mantle material and the hydrosphere/atmosphere. I suggest that it is this change that allowed SO₄²⁻ to become a major component of ocean water and the entry of significant amounts of free oxygen into the atmosphere.

I thank many South African geologists for cooperation and hospitality, in particular, Professor C. R. Anhaeusser, Professor D. A. Pretorius, Dr N. J. Beukes, Professor A. O. Fuller, Dr G. L. Coetzee, P. A. Harrison, Dr W. E. L. Minter, Dr T. G. Molyneux, P. R. Strydom, J. L. Matthysen, P. J. Schoeman, J. P. van Zyl, K. J. Barnard, T. Hopkins, M. Wuth, J. Wigand, P. Becker, L. N. J. Engelbrecht, and Dr P. J. Smit. The isotopic analyses were done by Dr R. Reesman. I thank the Geological Survey of Canada for support, and Professor R. M. Garrels for stimulating discussion on the geochemistry of sulphur.

Pheromones in mice: reciprocal interaction between the nose and brain

E. B. Keverne & C. de la Riva

Department of Anatomy, University of Cambridge, Downing Street, Cambridge CB2 3DY, UK

Blockade of pregnancy by odours from strange males¹⁻³ has interested considerably those that adopt a sociobiological approach to reproduction⁴⁻⁶. It has been suggested that the mechanism has evolved to promote heterogeneity in the population, and that strange males in possessing the capacity to block pregnancy thereby increase their reproductive potential. However, such knowledge as we have of the territorial behaviour and social organization of mice makes this explanation less likely as resident males have such an advantage over intruders that access by strange males is probably an infrequent event. Another explanation relates pregnancy block to the effect that the male pheromones have on the female reproductive hormones in other contexts. Male pheromones can stimulate both early puberty and induction of oestrus 10-12 in grouped females by suppressing prolactin secretion. Such a response, highly appropriate in this context, would be extremely disadvantageous following fertilization, since lowering prolactin is known to prevent implantation^{13,14}. Thus, some mechanism must exist to offset the more general effect of the male's own pheromone on the endocrine function of his female at such times, and this, we suggest, is prevented by the noradrenergic mechanism which we describe here.

In the first experiment, female mice (BALB/c), which had been housed alone for part of the experiment, were taken from their home cage and placed with BALB/c stud males for 20 min to allow mating. They were then removed to cages containing F₁ male bedding while the stud male was returned to the females' home cage. The F₁ males were derived from crossing C57 females with CBA males, and produce pheromones that

Table 1 Effect of replacing stud male odours immediately after mating on stud males' ability to block premancy

Stud male	Exposure to soiled bedding (0-48 h)	Exposure to male (48-72 h)	% Showing pregnancy block (n)
BALB/c BALB/c BALB/c BALB/c BALB/c	F ₁ BALB/c BALB/c F ₁ F ₁	BALB/c BALB/c F ₁ F	75 (8) — 0 (8) — 80 (10) — P < 0.01 — NS*

^{*} The data were subjected to χ^2 test of significance NS, not significant.

are sufficiently different from those of BALB/c males to prevent pregnancy occurring in BALB/c females. After 48 h the females were returned to their home cages containing the stud males. The control group consisted of females that were treated in the same way, except that, after mating, they were moved to cages containing BALB/c male bedding. Vaginal smears were taken daily to determine the onset of oestrus and 6 days after mating, females were killed and their uteri examined for implantation sites to demonstrate whether an olfactory block to pregnancy had occurred. The control females, which had been returned to the stud male after previous exposure to bedding from the same strain (BALB/c) showed implantation, as expected (Table 1). However, in those females exposed to F₁ male bedding for 48 h after mating, the stud male appeared to have been transformed to a 'strange' one, for subsequent exposure of the females to the stud male prevented implantation of his own fertilized

Neither exposure to F_1 bedding by itself for 48 h immediately after BALB/c mating nor a return to F_1 males after this procedure had any blocking effect on pregnancy. This experiment demonstrates that the odour cues which follow mating are the ones 'recognized' by the female's neuroendocrine system, and that this recognition is necessary for pregnancy block to occur. Stud males can thus cause fetal resorption, providing the female has received prolonged exposure to the odour of a strange male, replacing that of the stud.

How does the act of mating and exposure to odour immediately afterwards 'print' recognition of the stud male, thereby preventing him from blocking his own pregnancy? It is known that the so-called primer effects of such pheromones are transmitted by the vomeronasal accessory part of the olfactory system^{9,12,14-16}, which projects to the cortico-medial amygdala¹⁷ part of the brain closely related to the ventromedial hypothalamus, itself concerned with neuroendocrine activity. Both the accessory and main olfactory bulbs receive a noradrenergic projection¹⁸, and this system has been implicated in certain forms of recognition, for example the modulation of neural activity after exposure to certain types of visual stimuli early in life¹⁹, and the neuroendocrine response of the female rat to tactile stimuli inducing lordosis and pseudopregnancy²⁰.

To determine whether the centrifugal noradrenergic projection to the olfactory bulbs was involved in the response of the female mice to the males' pheromones, discrete lesions were made by stereotaxically injecting the neurotoxin 6-hydroxydopamine (2 µg 6-OHDA in 0.5 µl saline containing 2 µg ml⁻¹ ascorbic acid for 5 min) bilaterally into the medial olfactory

stria which carry the noradrenergic input to the olfactory and accessory olfactory bulbs. A second group of mice were injected in the same way with vehicle alone, a third group with neurotoxin directly into the accessory olfactory bulb, and a fourth group received no injections. After at least 4 days, females from each group were housed in pairs with a BALB/c stud male, which was removed the morning after mating had occurred (as assessed by observing vaginal plugs in the female); 24 h later the stud male was returned to the fertilized female and housed with her for 48 h. A fifth control group received 6-OHDA lesions to the medial olfactory stria but were kept away from all males after mating to determine whether the procedure itself interfered with pregnancy. Vaginal smears were taken daily, all females were killed 6 days after mating and the uterus examined for implantation sites; the olfactory and accessory olfactory bulbs were removed and their noradrenaline content measured.

Both groups 1 and 2 (female mice in which noradrenaline had been depleted in the accessory olfactory bulbs) failed to 'recognize' the stud male, and thus pregnancy was blocked by exposure to him, whereas the neurotoxin lesion itself (group 5) did not interfere with pregnancy (Table 2). As expected, in mice undergoing either sham operations or no treatment (groups 3 and 4), the stud male failed to block pregnancy. Measurement of the noradrenaline content showed that 6-OHDA lesions of the medial olfactory stria produced a significant decrease in noradrenaline (70%) in the olfactory and the accessory olfactory bulbs, without significantly altering dopamine (Table 2). Direct measurement of noradrenaline content in the accessory olfactory bulb was not possible because of its small size.

These experiments show that, in contrast to what is generally believed, a special neuromechanism exists not so much to ensure that strange males will block pregnancy in female mice, but so that familiar (that is, stud) males will not do so. This implies that some neural protective mechanism must be set in motion during mating which ensures that continued presence of the stud male or his odour after coitus will not prevent subsequent implantation. Such a process is dependent on olfactory input to the female which outlasts the act of coitus itself, as we have shown that it can be overridden by a second olfactory stimulus applied immediately after mating has occurred. For the neural mechanism to be effective, there must exist an intact noradrenergic input to the accessory olfactory bulb. The action of this noradrenergic mechanism in the olfactory system may be similar to that of other sensory systems, serving to enhance recognition of the stud male by increasing the signal-to-noise i1,22. Alternatively, it has been suggested that noradrenergic mechanisms may have an important role in the memory of events which have survival value²³, a 'print-now' mechanism for incoming sensory information to be stored for later retrieval¹⁹.

The response to male pheromones in female mice has selective advantages for accelerating puberty and induction of oestrus^{7,8}, but carries a risk for pregnancy should contact with these pheromones occur during a 3-day period after mating. The noradrenergic mechanism apparently sets in motion a relatively short-term neuroendocrine memory, which protects the female from pregnancy block which would otherwise be induced by her stud male.

Table 2 Effect of olfactory noradrenergic lesions in the female mouse on the stud males' ability to block pregnancy

Group	Treatment	•	% Showing pregnancy block (n)
1 2 3 4 5	6-OHDA (medial olfactory stria) 6-OHDA (accessory olfactory bulb) Sham lesion No treatment 6-OHDA (medial olfactory stria)	Re-exposure to stud male No male exposure	88 (8) 100 (8) - NS 12 (8) - P < 0.01* 0 (8) - NS

Mean noradrenaline content of olfactory bulbs in groups 3 and 1 was 0.37 ± 0.08 and 0.11 ± 0.07 ng per mg tissue, respectively, t=6.59; P<0.0004 Mean noradrenaline depletion = 70% Dopamine content of olfactory bulbs in groups 1 and 3 was 0.58 ± 0.2 and 0.38 ± 0.06 ng per mg tissue, respectively (t=0.82, not significant).

^{*} The data were subjected to χ^2 tests of significance.

We thank Anne Lloyd-Thomas, Barry Everitt, Gerald Moore and Joe Herbert for thought-provoking discussion.

Extensive elongation of axons from rat brain into peripheral nerve grafts

Martin Benfey & Albert J. Aguayo

Neurosciences Unit, The Montreal General Hospital and Department of Neurology, McGill University, 1650 Cedar Avenue, Montreal, Canada H3G 1A4

The failure of axons to elongate in the injured central nervous system (CNS) of adult mammals restricts drastically the establishment of connections with target tissues situated more than a few millimetres away. Mechanisms that include a primary inability of some nerve cells to support renewed axonal growth, a premature formation of synapses on nearby neurones¹, an obstruction caused by the formation of a glial scar^{2,3} and other influences of the microenvironment4-7 are presumed to contribute to the failure of nerve fibres to regenerate as effectively in the CNS as in the peripheral nervous system (PNS). Support for the hypothesis that conditions in the glial environment of injured fibres have a decisive role in successful axonal elongation has recently come from studies using transplants containing either central glia or peripheral nerve segments as conduits of axon growth^{7,8}. While CNS glial grafts have been shown to prevent growth of PNS fibres^{7–9}, experiments which used labelling techniques to trace the source of axons growing into PNS grafts provided evidence that processes from nerve cells in the spinal cord and medulla oblongata of adult rats may increase in length by 1 or more centimetres when the CNS glial environment is replaced by that of peripheral nerves 10,11. Here we report for the first time the extensive elongation of axons from neurones in the brain of adult rats through PNS grafts introduced into the cerebral hemispheres.

In 20 Sprague-Dawley rats weighing ~300 g the end of a 15-mm segment of an autologous sciatic nerve was inserted close to the basal ganglia or to the cerebral cortex (Fig. 1A). The animals had previously been anaesthetized with sodium pentobarbital administered intraperitoneally (5 mg per 100 g body weight). A glass rod held in a micromanipulator was inserted through an opening in the frontal bone and dura to a depth calculated to produce lesions extending to the sensory cortex or basal ganglia. The sciatic nerve graft was then introduced into each of these lesions and its epineurium anchored to the dura mater with 10-0 nylon sutures. The space between the nerve and the surrounding skull was sealed with bone wax and the free outer end of the nerve sutured to the temporalis muscle. The animals survived without any apparent neurological deficit other than limb weakness resulting from the removal of one sciatic nerve. The rats were examined 5-23 weeks after grafting to determine whether axons from neurones within the brain had elongated along the graft. For this purpose the graft was dissected along its extracranial course, transected 2 mm from its insertion into the temporalis muscle, and the free end placed for 50 min in a pad of Gelfoam soaked in a 20% solution of horseradish peroxidase (HRP; type VI, Sigma). The remaining portion of the graft was placed over a plastic sheath and covered with vaseline to avoid contamination of the surrounding tissue by HRP (Fig. 1A). In five additional animals, used as controls, the mid-portion of the regenerated graft was crushed three times with fine-tip forceps cooled in liquid nitrogen, 9-16 weeks after grafting and half an hour before the application of HRP to the distal end of the crushed nerve. About 48 h after applying HRP, the animals were perfused through the heart with a 0.1 M phosphate buffer solution followed by 3% glutaraldehyde. The brain was removed and rinsed in 10% sucrose buffer overnight. Then, 40 µm-thick coronal sections were cut in a cryostat, reacted with tetramethylbenzidine and hydrogen peroxide¹², counterstained with neutral red and mounted in Permount.

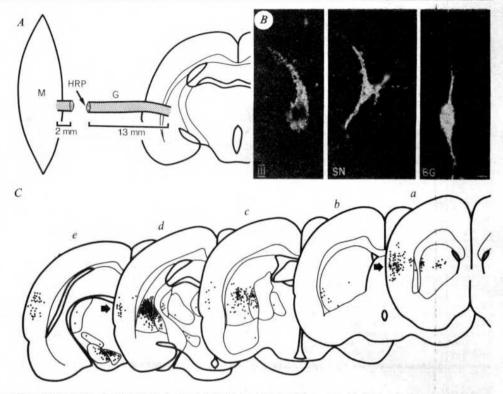

Cross-sections of the outermost portion of each graft were examined using a light microscope and found to contain regenerated fibres surrounded by Schwann cells and myelin. The overall appearance of these fibres resembled that of any regenerated peripheral nerve. HRP-labelled neurones were sought by dark- and brightfield light microscopy in sections rostral to and including the midbrain. An average of 145 sections of the brain were examined per rat. In 10 experimental animals the graft terminated close to the cortex; in 8 it was found within the caudate putamen and in 1 rat each it reached the hippocampus or the ventral nucleus of the thalamus. Of a total of 444 HRP-labelled neurones (Fig. 1B, C), most were found in the caudate putamen and sensory cortex (Table 1). The labelled nerve cells in the sensory cortex were scattered through layers II-VI. Both large and small cortical neurones were labelled but the HRP-containing cells tended to be of larger size than the unlabelled ones in the same regions (Fig. 2). Most (79%) of the labelled cells found in the brain of these animals were within 1.5 mm of the intracerebral tip of the graft; the rest were located between 1.5 and 6.5 mm from the graft. The greatest distance between the graft and the soma of the labelled cells was found for neurones in the substantia nigra (SN). Because all labelled neurones in the experimental rats were confined to a well circumscribed area close to the graft and as only two neurones were labelled in the five controls in which the graft was crushed before HRP application, we believe that most of the cells in the experimental animals used in this study were not falsely labelled by haematogenous spread or by diffusion along the grafted nerve. Thus, on the basis of these HRP tracing studies, we conclude that axons of cells in different regions of the rat brains examined have become elongated by at least 13 mm, the length of nerve graft used in the labelling experiments.

The fact that the largest number of labelled neurones was found in the caudate putamen may reflect a greater ability of

Table Distribution of HRP-labelled cortical and subcortical neurones in the brain of rats having PNS grafts

Site	No. of HRP- labelled neurones
Caudate putamen	218

Amygdala	1
Claustrum	1
Cortex	126
Total	444

Fig. 1 A, Schematic representation of the experimental design: a PNS graft (G) has been introduced into the rat brain. The intracranial tip of the graft can be positioned close to the cortex or subcortical nuclei within the hemisphere. The outer end of the graft, initially attached to the temporalis muscle (M), is cut to apply HRP. The advantages of this design are: (1) as most of the graft is extracranial, the cells from which the axons growing into the graft have originated can determined by retrograde labelling with little risk contamination from spread of HRP into the brain; (2) the length of axons regenerating within the graft can be measured by determining the distance between the site of HRP application and the soma of the labelled cells; (3) the grafts may be positioned in several regions of the brain to test the regenerative capacity of different neuronal populations. B, darkfield light micrographs of HRPlabelled neurones in layer III of the sensory cortex, from the pars compacta of the substantia nigra (SN) and from basal ganglia (BG).

Calibration bar, $10 \mu m$. C, transverse sections of the brain, obtained at 1.5-mm intervals, are arranged in a rostral (a) to caudal (e) direction to illustrate the approximate position of the 444 labelled neurones (\bullet) observed in 20 grafted animals. The arrow in d indicates the site of 15 graft insertions made stereotactically 4.4 mm rostral to the inter-aural line in the horizontal plane¹⁹. In five other animals the graft was inserted 9 mm rostral to and 2 mm above these two reference lines (arrow in a).

these cells to regenerate in the experimental conditions used, or may simply be the consequence of their proximity to the transplanted nerve; different graft locations may elucidate this question. Most of the labelled cerebral neurones were situated near the tip of the graft, which suggests that the remarkable elongation of their axons results from local sprouting triggered by injury 13-15 resulting from the grafting procedure and facilitated by growth-favouring conditions in the PNS transplant. It is also possible that growth factors released by the segment of nerve 16,17 may influence only the soma of nearby cells. The demonstration that the cerebral neurones that give rise to the re-growing axons are confined to an area within a few millimetres of the end of the graft is consistent with similar observations in the rat spinal cord and brain stem10,11. These findings suggest that it may be possible to use similar grafting methods to investigate further neuronal plasticity in other specific areas of the CNS of mature and immature animals and in conditions associated with ageing and disease.

Although the axons of neurones labelled in these experiments would, in the intact animal, reside and project exclusively within the CNS, they have successfully elongated along the implanted grafts in a manner similar to that of fibres injured in peripheral nerves. This indicates that such elongation may depend on properties shared by populations of intrinsically and extrinsically projecting nerve cells, the potential for the growth of intrinsic CNS neurones being expressed when the neuroglial environment in the brain is substituted by that in peripheral nerves. It is not known, however, whether the cells labelled in these experiments indicate a more general potential for regeneration by CNS neurones when interacting with Schwann cells and other PNS components.

These results also suggest that in conditions created by nerve grafting, the axons of some CNS neurones can grow to lengths greater than those normally reached in the intact animal. Axons from the striatal neurones, which are thought normally to project only to the nearby globus pallidus and SN¹⁸, appear to have grown along the entire length of the grafts. Furthermore, because the intracerebral tip of the 13-mm-long graft was as far as 6.5 mm from the labelled SN cells in some animals, we

calculate that the axons from nigral neurones must have attained a total length of almost 20 mm. The extent of this axonal growth can be placed in perspective by comparing it with the maximum direct distance between the SN and the cerebral cortex: 14–15 mm in 300 g rats¹⁹.

The hypothesis that the microenvironment at the tip of the

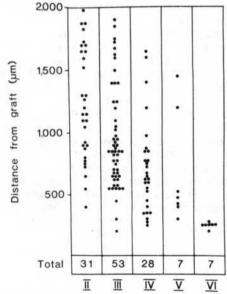

Fig. 2 Distribution of 126 HRP-labelled neurones in layers II-VI of the somatosensory cortex of grafted rats. The vertical axis indicates the distance between the labelled soma and the intracerebral tip of the graft. The cells in the more superficial layers are nearly 2 mm from the graft. The diameter of the labelled cortical neurones averaged 24.9 \pm 4.05 μm (mean \pm s.d.) (range 16.8-38.4 μm) while that of 250 unlabelled neighbouring cells was 17.9 ± 3.63 μm (range 12.0-28.8 μm). The difference in size between the labelled and unlabelled cells may result from a neuronal reaction to axon interruption at the time of HRP application to the graft.

re-growing axon has a decisive role in the success or failure of regeneration implies that non-neuronal PNS components influence neuronal mechanisms that regulate elongation²⁰ whereas the CNS milieu of adult mammals either lacks these growth-promoting factors or exerts an inhibitory influence. The critical differences between the CNS and PNS microenvironment are unknown but may include specific substances released by cells^{6,22}, influences arising from extracellular components²³, surface properties of sheath cells²⁴ and, possibly the different spatial arrangement of glia in the CNS and PNS. Further questions which require investigation are whether central axons elongate into PNS grafts by the regrowth of the damaged fibres, by collateral sprouting or by both. Will long projecting axons

such as those of the corticospinal tract, also grow along PNS grafts after they are interrupted in the brain? What connections, if any, can be established between the growing CNS axons and the target tissues to which the nerve graft is attached? Our findings suggest that the elongation of axons from these central neurones is governed by interactions between the growing nerve fibres and their surrounding tissues, and that abortive regeneration is not the result of an intrinsic lack of neuronal potential to support renewed growth.

Functional synapses are established between ciliary ganglion neurones in dissociated cell culture

Joseph F. Margiotta & Darwin K. Berg

Department of Biology, University of California, San Diego, La Jolla, California 92093, USA

The formation of specific synaptic connections is a central part of development in the nervous system. The parasympathetic ciliary ganglion of the chick is a useful population of neurones for studying synaptogenesis both because its development has been well characterized in vivo¹ and because its neurones can be maintained and examined in long-term dissociated cell culture^{2,3}. The ciliary ganglion contains two classes of neurones: choroid neurones that innervate smooth muscle in the choroid layer of the eye, and ciliary neurones that innervate striated muscle in the iris and ciliary body. Both classes of neurone are cholinergic and both receive excitatory cholinergic input from preganglionic neurones in the accessory oculomotor nucleus. Ciliary ganglion neurones do not seem to innervate each other in $vivo^{4.5}$, even though they have matching neurotransmitter and receptor types. In cell culture, the neurones acquire high levels of choline acetyltransferase activity, form cholinergic synapses on skeletal myotubes when present in the cultures, and have significant levels of acetylcholine (ACh) sensitivity2,6, as they do in vivo. We report here that cholinergic synaptic transmission does occur between the neurones in cell culture. These results indicate that ciliary ganglion neurones can innervate each other, and suggest that additional constraints exist in vivo to prevent them from doing so.

Dissociated ciliary ganglion neurones were obtained from $7\frac{1}{2}$ -day-old chick embryos and, unless otherwise indicated, were grown in 35-mm dishes with skeletal myotubes as previously described². In some cases the neurones were grown alone, using a collagen substratum coated with fibroblast material². Culture medium was as previously described for nerve-muscle cultures² except that some cultures of neurones alone received medium with 3% (v/v) embryonic chick eye extract instead of 5% (v/v) whole embryo extract². After 5-14 days the neurones were

examined using intracellular recording techniques2,6; microelectrodes were filled with 1 M potassium acetate and had tip resistances of 80-200 M Ω . Recordings were accepted only if impaled neurones had resting potentials exceeding -45 mV and fired impulses in response to intracellular stimulation.

Intracellular recordings from the neurones revealed discrete spontaneous depolarizations that ranged in amplitude over 0.5-15 mV and in half rise time over 0.6-1.2 ms, and appeared to decay exponentially (Fig. 1). The frequencies of such depolarizations among neurones varied from 2 to 300 per min and persisted throughout recordings that lasted up to 45 min. At high frequencies the depolarizations often summed and occasionally triggered action potentials in the neurones (Fig. 1). Over 90% of the neurones grown with myotubes displayed such depolarizations whereas only 42% of the neurones grown alone did so (Table 1).

Pharmacological experiments indicated that the spontaneous depolarizations were cholinergic in origin. Perfusion of the cultures with 25 μM(+)tubocurarine (TC) completely abolished the depolarizations in all neurones within 5 min; partial recovery of the spontaneous activity was obtained 4 min after washout of the drug was initiated (Fig. 2). After 30 min of washout, the occurrence of depolarizing potentials among randomly selected, treated neurones was indistinguishable from that obtained in control cultures (Table 1).

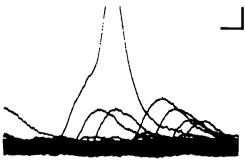

Fig. 1 Spontaneous depolarizations recorded in a ciliary ganglion neurone grown with myotubes. A number of oscilloscope traces have been superimposed showing about 15 depolarizations. In one case a depolarization has triggered an action potential. Resting potential: -61 mV. Calibration bars: vertical, 5 mV; horizontal, 2 ms.

Fig. 2 Reversible blockade of the spontaneous depolarizations by (+)tubocurarine. a, Spontaneous depolarizations in a ciliary ganglion neurone grown with myotubes; b, blockade of the depolarizations in the same neurone 4 min after the initiation of perfusion with 25 μM TC; c, recovery of the depolarizations in the same neurone 4 min after washout of the TC was initiated by perfusion with normal medium. Resting potential: -60 mV. Calibration bars: vertical, 20 mV; horizontal, 2 s.

The spontaneous depolarizations were also blocked by the α -neurotoxin Bgt 3.1 which has previously been shown to block the ACh sensitivity of ciliary ganglion neurones in cell culture^{6,7}. Neurones incubated with 20 nM Bgt 3.1 for 1 h at 37 °C were never seen to display the spontaneous depolarizations (Table 1). Recovery of the responses was observed after removal of the Bgt 3.1 (Table 1). During TC or Bgt 3.1 treatment, the neurones remained able to fire action potentials when stimulated intracellularly, and had resting potentials not significantly different from those recorded in normal medium (P > 0.25, Student's t-test).

 α -Bungarotoxin (Bgt 2.2), which inhibits ACh receptors on muscle cells but not ACh receptors on ciliary ganglion neurones⁶, did not block the spontaneous depolarizations observed in the neurones. After a 1-h incubation in 10 nM Bgt 2.2, most of the neurones tested still displayed the spontaneous potentials (Table 1). The Bgt 2.2 treatment was effective, however, at blocking muscle ACh receptors, because the normally twitching myotubes in the nerve-muscle cultures were quiescent after the incubation with Bgt 2.2. Intracellular recording demonstrated that the synaptic potentials normally observed in the myotubes were absent. These results indicate

Table 1 Incidence and pharmacological blockade of spontaneous depolarizations in ciliary ganglion neurones

Culture type	Drug treatment	% Neurones with spontaneous depolarizations
Nerve-muscle	None	92 (60, 12)
Nerve	None	42 (24, 8)
Nerve-muscle	TC	0 (13, 6)
	TC removed	93 (14, 6)
Nerve-muscle	Bgt 3.1	0 (13, 3)
	Bgt 3.1 removed	83 (6, 2)
Nerve-muscle	Bgt 2.2	82 (11, 2)

Ciliary ganglion neurones were grown with skeletal myotubes (nervemuscle) or grown alone (nerve), and incubated with the indicated drug for 1 h at 37 °C, and then examined in the same conditions for spontaneous depolarizations as described in the text for a period of at least 3 min per neurone. The mean resting potential was -56 ± 1 mV (\pm s.e., n = 80). The proportion of neurones with spontaneous depolarizations is presented as a per cent of the neurones tested; the number of neurones tested and the number of cultures sampled are shown in parentheses. Drug concentrations were TC, 25 µM; Bgt 3.1, 20 nM; and Bgt 2.2, 10 nM. For one of the TC cultures, 25 µM hexamethonium was included and the TC concentration was 100 µM. Recovery from TC treatment was followed in the same cultures used to test the effects of TC: at the end of the TC test period the cultures were rinsed and incubated for 0.5 h at 37 °C and then re-examined (TC removed). As for recovery from Bgt 3.1, cultures previously tested in Bgt 3.1 were rinsed and incubated for 2 h at 37 °C and then re-examined (Bgt 3.1 removed). In all cases the cultures were also tested before drug treatment to verify that the neurones displayed the expected incidence (~90%) of spontaneous depolarizations.

that the spontaneous depolarizations observed in the neurones are not in some way dependent on neurogenic muscle contraction, a conclusion also implied by the presence of the depolarizations in neurones grown alone.

The pharmacological experiments indicate that the spontaneous depolarizations recorded in the neurones represent cholinergic excitatory postsynaptic potentials. They can be reversibly blocked by TC and Bgt 3.1, and are not blocked by Bgt 2.2. A similar pharmacology has been described for ACh receptors on the neurones⁶. The implication is that ciliary ganglion neurones establish synapses on each other in cell culture and that neurotransmitter release can occur spontaneously or be evoked by spontaneous action potentials in the presynaptic neurone. Synapses between ganglionic neurones have also been described for rat sympathetic neurones in cell culture when the cells are induced to become cholinergic^{8,9}.

Morphological evidence for chemical synapses between ciliary ganglion neurones in culture has been reported previously, but stimulation of the neurones failed to evoke synaptic transmission¹⁰. We routinely test neurones for electrical excitability by using intracellular stimulation to trigger action potentials. We have occasionally seen depolarizations produced in a neurone following action potentials elicited in the same neurone. The evoked depolarizations were phase-locked to the action potentials with a fixed time delay and, in the case of one neurone, were adequate to elicit a second action potential (Fig. 3). Although we have not demonstrated that the evoked depolarizations can be blocked by cholinergic antagonists, they do have the range of amplitude and half rise time described above for the synaptic potentials. Studies with tetrodotoxin (TTX) support the possibility that evoked transmission does occur between the neurones. Perfusion of nerve-muscle cultures with 10 μM TTX for 2 min completely abolished the spontaneous synaptic potentials (eight neurones, three cultures); rinsing the cultures with medium lacking TTX for 4 min resulted in the reappearance of synaptic potentials in four out of five neurones tested (three cultures). These results are consistent with the synaptic potentials being elicited by spontaneous TTX-sensitive action potentials which we frequently observed while recording from the neurones (unpublished observations). To determine whether evoked transmission can be reliably obtained at synapses capable of spontaneous transmission, however, it will be necessary to identify transmitting neurone pairs and to test them with intracellular stimulation.

The difference in the proportion of neurones showing synaptic potentials in nerve compared with nerve-muscle cultures (Table 1) could reflect differences in the frequency of action

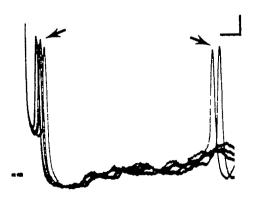

Fig. 3 Recordings from a neurone grown with myotubes showing evoked depolarizations occurring with a fixed time delay after an action potential. Five superimposed oscilloscope traces are shown. In each case a brief (0.1 ms) intracellular current pulse was used to trigger an action potential (arrow, left) in the impaled neurone. After a delay of ~10 ms, a series of depolarizations was observed. In two of the five trials the depolarizations triggered a second action potential (arrow, right). The nearly vertical line at the far left marks the stimulus artefact. Resting potential: -58 mV. Calibration bars: vertical, 10 mV; horizontal, 5 ms.

potentials in presynaptic neurones or differences in the number or efficacy of synapses in the two kinds of cultures. The presence of myotubes as a synaptic target for the neurones clearly does not prevent the neurones from also forming synapses on each other.

Although it remains possible that ciliary ganglion neurones transiently innervate each other at early stages in vivo, it seems clear that they normally do not do so in the adult chick or pigeon^{4,5}. Recently it has been shown that parasympathetic neurones of the frog cardiac ganglion which also do not normally innervate each other, can do so in vivo when deprived of their normal preganglionic input; reinnervation of the neurones by the preganglionic fibres leads to suppression of the synapses between ganglionic neurones¹¹. The formation of synapses between ciliary ganglion neurones in culture may also reflect the absence of their normal preganglionic fibres.

Growth factors adherent to cell substrate are mitogenically active in situ

J. C. Smith*, J. P. Singh, J. S. Lillquist, D. S. Goon & C. D. Stiles

Laboratory of Tumor Biology, Sidney Farber Cancer Institute, and Department of Microbiology and Molecular Genetics, Harvard Medical School, Boston, Massachusetts 02115, USA

We report here that platelet-derived growth factor (PDGF)1-4 and pituitary-derived fibroblast growth factor (FGF)5 bind rapidly and tenaciously to tissue culture plates either coated with collagen (a major component of the extracellular matrix) or uncoated. Surface-bound PDGF resists extraction with nonionic detergents, organic solvents and chaotropic solvents: moreover it is biologically active in situ. Our finding that immobilized PDGF is nonetheless mitogenic lends support to other observations which indicate that PDGF functions outside the cell via production of a stable intracellular second signal⁶. In a broader context, the observations suggest that one role of the extracellular matrix in vivo is to sequester biologically active molecules like PDGF to provide a localized and persistent

PDGF was purified to homogeneity and radioiodinated as described in Table 1 legend. Binding studies with 125I-PDGF (see Table 1 legend) showed that the radiolabelled material binds to specific receptors on the surface of confluent BALB/c-3T3 cell monolayers. We and others have found that most of

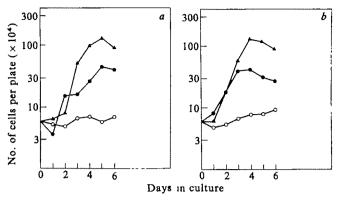

Fig. 1 PDGF-treated plates support continued proliferation of BALB/c-3T3 cells in medium containing platelet-poor plasma. Tissue culture plates (35 mm), either coated with collagen or uncoated, were exposed to 500 units ml⁻¹ of heat-treated PDGF³ at 37 °C for 4 h. Control plates were not treated with PDGF. BALB/c-3T3 cells (6×10^4) were seeded on to each plate in medium containing 5% platelet-poor plasma and cell numbers were determined daily; cells were fed every other day. For comparison, the growth of cells on untreated plates in medium containing 5% calf serum is shown. a, Collagen-coated plates: •, 5% plasma, PDGF-treated plates; O, 5% plasma, untreated plates; A, 5% serum, untreated plates. b, Uncoated plates: symbols as in a.

the 125I-PDGF bound to confluent monolayer cell cultures is cell associated. In the absence of a cell monolayer, however, 12 PDGF binds to the surface of empty tissue culture plates in a non-saturable manner. In the experiments summarized in Table 1, 125I-PDGF (20 ng ml-1) was placed over the surface of empty microtitre tissue culture wells and incubated at 37 °C for 1 h. In these conditions about 1 ng of PDGF becomes associated with the surface of the culture dish, and this surface-bound PDGF resists extraction with various strong solvents. We found that boiling SDS is partially effective in extracting the bound PDGF, and pronase solubilizes ~70% of the radioactivity. From the molecular weight of PDGF (33,000-35,000)3.4 it can be calculated that the empty tissue culture wells bind between 6×10^{10} and 9×10¹⁰ molecules of PDGF per cm². Although the absolute amount of PDGF bound is small, a 3T3 cell (spread surface area 2×10^{-5} cm²) plated on to a culture dish pretreated with PDGF could be presented with between 3×10^5 and 4.5×10^5 molecules of PDGF from below. This is well in excess of the number of molecules needed to saturate cellular PDGF receptors (see Table 1 legend).

When quiescent 3T3 cells were plated out in culture dishes that had been pretreated with PDGF, DNA replication was induced in the absence of any PDGF added to the medium (Table 2), thus PDGF bound to the surface of tissue culture dishes is mitogenically active. F6F, which is a functional analogue of PDGF for stimulating the growth of BALB/c-3T3 cells⁸, also retained its mitogenic activity when bound to tissue culture dishes (Table 2). The concentrations of pure PDGF or partially pure FGF which delivered a mitogenic quantity of growth factor to the surface of empty tissue culture plates (Table 2) were of the same order of magnitude as those used to stimulate cell growth in conventional conditions^{3,5}. The mitogenic activity of PDGF fixed to the surface of tissue culture plates resisted extraction with 6 M urea, methanol, ethanol and glycine-EDTA (pH 10) as well as Triton X-100 (Table 3), but was totally abolished by reduction with 2-mercaptoethanol or digestion with proteases, as is the activity of soluble PDGF3. In agreement with the data of Table 1, boiling 1% SDS partially removed or inactivated the surface-bound PDGF.

We demonstrated that surface-bound PDGF is biologically active in situ in the following way. One-half of an empty tissue culture plate was exposed to PDGF by tilting the plate during treatment. The plate was washed with phosphate-buffered saline (PBS) and then 3T3 cells were seeded over the entire plate at a density of 7×10^4 cm⁻² in medium containing 5% plasma

^{*}Present address Imperial Cancer Research Fund, Mill Hill Laboratories, Burtonhole Lane, London NW/IAD, UK

and ³H-TdR. The culture plate was incubated for 42 h, fixed and processed for autoradiography. The amount of labelling on the treated side of the plate was 42%, that on the untreated side 7%. Hence, the mitogenic activity of PDGF-treated plates is predominantly a local effect.

Surface-bound PDGF supports repeated cycles of cell growth and division as well as localized induction of DNA synthesis. We compared proliferation of BALB/c-3T3 cells on four substrates (plastic, collagen, plastic pre-treated with PDGF, and collagen pre-treated with PDGF) in medium containing 5% plasma (Fig. 1). Cells maintained on plastic or collagen proliferated only

Table 1 Binding of ¹²⁵I-PDGF to the surface of tissue culture dishes

PDGF-treated plates extracted with:	c.p.m. ¹²⁵ I remaining on surface of dish
PBS	10,806
Triton X-100 (0.5%)	11,389
Methanol (95%)	12,896
Ethanol (95%)	12,362
Urea (6 M)	15,495
SDS (1%) (100 °C)	7,963
Pronase (2 mg ml ⁻¹)	3,760

PDGF was purified to homogeneity by a modification of our previous method³, then radioiodinated to a specific activity of 10,000 d.p.m. ng⁻¹ by a modification of the Hunter and Greenwood procedure¹⁸. The 125 I-PDGF retained its mitogenic activity. Studies of binding specificity to BALB/c-3T3 cells (performed at 4 °C) indicated that confluent monolayer cultures of BALB/c-3T3 possesses $\sim 8\times 10^4$ PDGF receptors per cell. Nanogramme per ml quantities of unlabelled PDGF completely displaced the 125 I-PDGF from these surface receptors whereas microgramme per ml quantities of epidermal growth factor or insulin had no effect. To measure the binding of 125 I-PDGF to the cell substratum, empty microtitre tissue culture wells (0.3 cm² surface area) were incubated with 40,000 c.p.m. of 125 I-PDGF in 200 µl Dulbecco's modified Eagle's medium (DMEM) with 1 mg ml $^{-1}$ of unlabelled bovine serum albumin as carrier. After 1 h.at 37 °C the 125 I-PDGF solution was aspirated. The microtitre plates were then extracted at 37 °C for 1 h with the indicated solvents (except for SDS which was a 1 min extraction at 100 °C). Following extraction the solvents were aspirated. The microtitre plates were again washed extensively with PBS and dried. The bottom of each microtitre plate was punched out and placed in a γ counter for determination of bound 125 I-PDGF.

Table 2 Mitogenic activity of surface-bound PDGF and FGF

	y plates with PDGF		y plates I with FGF
[PDGF] (ng ml ⁻¹)	% Labelled nuclei	[FGF] (ng ml ⁻¹)	% Labelled nuclei
40 20 10	94.9 95.2 83.2	1,000 300 100	91 65 58
2.5 0	65.3 24.5	30 0	8 2

The mitogenic activity of surface-bound PDGF and FGF was detected by induction of DNA synthesis in quiescent 3T3 cells. Empty microtitre tissue culture wells were precoated with collagen (collagen dispersion TD-150: Ethicon, Massachusetts) to facilitate rapid cell attachment. The collagen-coated plates were then pretreated with the indicated concentrations of electrophoretically pure PDGF (prepared by a modification of a previous protocol3) or partially purified pituitary FGF (KOR Biochemicals, Massachusetts) at 37 °C for 4 h. The plates were rinsed twice with PBS and further extracted at 37 °C for 1 h with 0 5% Triton X-100 as described in Table 1 legend. Quiescent density-arrested BALB/c-3T3 cells were collected by trypsin digestion and immediately replated at a density slightly greater than their confluent density (\sim 7× 10⁴ cells cm⁻²) into the treated microtitre culture wells. The cultures were incubated at 37 °C for 36 h in medium containing ³H-thymidine (5 μC₁ ml⁻¹) and 5% platelet-poor plasma (which lacks PDGF¹) cultures were then fixed and processed for autoradiography. Per cent labelled cells was determined for each well.

Table 3 Mitogenic activity of surface-bound PDGF after extraction with various solvents and enzymes

PDGF-treated plates extracted with:	% Labelled nuclei ±s.d.
Triton X-100 (0.5%)	$66 \pm 20 \ (n=8)$
Glycine (10 mM; pH 10.0)	88±5 (3)
Methanol	$92 \pm 5 (2)$
Ethanol	$84 \pm 4 (2)$
Urea (6 M)	$68 \pm 17 (3)$
RNase $(30 \mu \text{g ml}^{-1})$	$77 \pm 5 (2)$
DNase $(10 \mu \text{g ml}^{-1})$	$74 \pm 5(2)$
Acetic acid (1 M) (pH 2.3)	$46 \pm 12 (3)$
SDS (1%; 100°C)	$40 \pm 32 (3)$
Urea (6 M) +2-mercaptoethanol (10%)	$10\pm 8(2)$
Pronase (2 mg ml ⁻¹)	$0 \pm 5(3)$
Trypsin (1,000 U ml ⁻¹)	$19 \pm 17(2)$

The surface of empty tissue culture plates was exposed to partially purified PDGF³ in DMEM at 37 °C for 3-4 h. The PDGF concentrations used were in the range 50-500 units ml⁻¹ where 1 unit of activity = ~0.2 ng PDGF³. Control plates were treated with DMEM alone. After 3-4 h the solutions were aspirated. The empty wells were then washed and extracted with solvents as described in Table 1 legend. Surface-bound, biologically active PDGF was detected by induction of DNA synthesis in quiescent 3T3 cells as described in Table 2 legend. The nuclear labelling index of cells cultured on the treated plates is shown after subtracting the background of labelled nuclei on untreated plates; the background labelling ranged from 0 to 25% in individual experiments.

poorly in 5% plasma but grew rapidly for 3–5 days on substrate pre-treated with PDGF. Cells cultured with 5% plasma on PDGF-treated plates grew to slightly lower final densities than cells cultured conventionally in serum-containing medium; however, the cells cultured conventionally received three separate PDGF treatments (through the change of serum-containing medium on alternate days) whereas the cells cultured on PDGF-treated plates were subject to only one PDGF treatment. We have obtained similar results by treating collagen-coated plates with pituitary FGF.

We conclude that PDGF and FGF adhere tenaciously to the surface of tissue culture plates; from this position, they can stimulate proliferation of cells maintained in platelet-poor plasma. These results may have a bearing on tissue culture analyses of extracellular matrix materials, and their role in controlling cell growth and function⁹⁻¹¹. The findings may also be relevant to the well characterized 'anchorage requirement' for fibroblast growth in vitro 12-14. It remains to be determined whether this has physiological relevance in vivo.

The induction of cell division by surface-bound PDGF is a highly efficient process as quantified by dose-response analysis, amount of PDGF consumed and duration of effect. If efficiency can be taken as a sign of biological relevance, these data suggest that fibroblast-like cells are intended to respond to PDGF presented in this manner. A functional interaction between PDGF and the cellular substratum in vivo can easily be rationalized. PDGF is a connective tissue mitogen which is also chemotactic for smooth muscle cells¹⁵; it is believed to have a role in wound healing and maintainence of the vascular system and may be involved in the genesis of atherosclerosis^{2,16,17}. If PDGF adheres to collagen surrounding the smooth muscle cells at the site of a wound, the mitogenic effect might be considerably prolonged. A gradient of PDGF concentration so produced (high near the wound, lower further away) might provide a directional cue for migrating cells. More generally, the adhesion of biologically active polypeptides to the extracellular matrix might serve to guide cell migration during embryogenesis or even provide a 'memory' of past developmental signals.

Selective effect of feline leukaemia virus on early erythroid precursors

D. Onions*, O. Jarrett*, N. Testa†, F. Frassoni† & S. Toth*

* Department of Veterinary Pathology, University of Glasgow, Bearsden Road, Glasgow G61 1QH, UK † Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester M20 9BX, UK

Feline leukaemia virus (FeLV), a horizontally transmitted retrovirus, is the aetiological agent of feline lymphosarcoma and leukaemia¹⁻³. In addition, the establishment of persistent FeLV viraemia in cats has been associated with the induction of a wide range of non-neoplastic conditions including immunosuppression, reproductive disorders and anaemias 4.5. FeLV isolates from cats may be divided into three subgroups, A, B and C, based on their interference patterns^{6,7}. In natural isolates, FeLV-C is always found in association with subgroups A or AB but the subgroup C component may be separated as a non-defective virus capable of establishing a persistent viraemia in neonatal cats. Pure red cell hypoplasia (PRCH) is one of three primary forms of FeLV-associated anaemia recognized in cats^{8,9} and we report here that three new biologically cloned FeLV-C isolates will reproduce this disease. We have demonstrated that infection of cats with FeLV-C/Sarma results in rapid depletion of early erythroid precursors (burst-forming units-erythroid; BFU-E) while the proportion of the myeloid precursor (granulocyte-macrophage colony-forming cells; GM-CFC) in the bone marrow remains normal.

In a survey of FeLV subgroups in naturally infected, viraemic cats, FeLV-C was not observed in 98 clinically normal animals but was isolated from 9 of the 32 (28%) anaemic cats examined. Subgroup C viruses from three of these anaemic cats were biologically cloned and used to infect neonatal kittens as described in Table 1 legend. Each isolate produced a PRCH that was clinically evident 3-6 weeks after infection. The pathology of the disease produced by these isolates resembled that previously described for FeLV-C/Sarma¹⁰

To determine the effect of subgroup C viruses on haematopoietic precursor cells, 3.5×10⁵ focus-inducing units (FIU) of FeLV-C/Sarma were inoculated intraperitoneally, within 24 h of birth, into specific pathogen-free randomly bred cats. A control group of uninfected cats was established from the same colony and members of both groups were bled weekly to determine their blood constituents and virus status¹¹. We detected viraemia in all the FeLV-infected cats except cat 7.

The control cats showed normal feline blood development¹² in that the haematocrit rose from a low value at 4 weeks until the adult level was attained at ~12 weeks (Fig. 1). In the infected cats, however, the rise in the haematocrit was not sustained but began to fall from 7 weeks onwards. Individual FeLV-Cinfected cats displayed episodes of splenic erythroid regeneration with the release of normoblasts into the circulation. These events were associated with a temporary slight rise in the individual's haematocrit before it fell to a new low level. Cat 7, which was not detectably viraemic, displayed normal blood development throughout the experiment.

Starting 3 weeks after infection and at intervals thereafter, the femoral bone marrow of the cats was assayed for the early erythroid precursor (BFU-E)¹³ and the neutrophil macrophage precursor (GM-CFC; refs 14, 15) (Table 2). The numbers of BFU-E and GM-CFC in all the control cats were within the range previously established for cats 3–12 months old (data not shown). Examination of the FeLV-C-infected cats, however, indicated that a dramatic reduction in the numbers of BFU-E cells had occurred as early as 3 weeks after infection while the incidence of GM-CFC was normal (Table 2). A reduction in BFU-E numbers in FeLV-C-infected cats has also been observed by others (J. Adamson, personal communication).

Both control and FeLV-C-infected cats exhibited splenic extramedullary haematopoiesis (EMH) which is a normal feature of feline haematopoiesis in cats of this age range. This process may have accounted for the normal haematological status of cat 7, which was not detectably viraemic but which showed extensive reduction of BFU-E in the bone marrow. The pattern of reduced BFU-E and normal GM-CFC levels was seen in the infected cats throughout the experiment, except

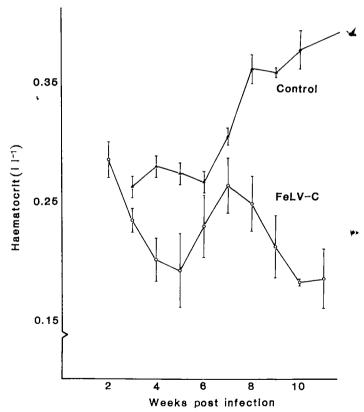

Fig. 1 Mean haematocrits (±s e) of control uninfected and FeLV-Sarma-infected kittens. A control group of 6 newborn kittens and 10 FeLV-C/Sarma-infected newborn kittens were established from the same colony. A separate group of three control and eight of the FeLV-C/Sarma-infected kittens were used in the colony assays described in Table 2 (cats 1-11). The kittens were bled weekly by jugular venepuncture and a 1-ml blood sample was used to establish the haematological values and the presence or absence of plasma viraemia as previously described¹¹ A comparison of the haematocrits of the FeVL-C-infected and control group by Wilcoxon's two-sample rank test indicated significant differences (0 01 level of T) at weeks 5, 8 and 9. From week 10 onwards only two kittens remained in the FeLV-C-infected group, precluding a statistical comparison.

Three new FeLV-C isolates, FZ215, FS246 and FA27, were biologically cloned, checked for subgroup-C specificity by interference assay and the titre determined as described previously¹¹. The pathogenicity of these isolates was determined by intrapernoneal inoculation to groups of four 1-day-old kittens with either 3.4×10^5 FIU of FZ215, 1.0×10^4 FIU of FS246 or an undetermined titre of FA27 (ref. 23). A group of six age-matched controls remained uninfected. The haematocrit and plasma viraemia were determined each week for 3 weeks. In a separate experiment (described in Fig. 1 legend) day-old kittens were either inoculated with FeLV-C/Sarma or uninfected (controls) and the weekly total leukocyte counts measured. The haematocrit and bone marrow colony assays for this experiment are given in Fig. 1 and Table 2, respectively. ND, not determined. — Experiment completed.

for cat 10 which, when killed at 11 weeks, had reduced GM-CFC. There may have been a limited effect of FeLV-C on GM-CFC but a simple interpretation of this effect was complicated by the occurrence of myelofibrosis and osteosclerosis. Although there was a marked reduction in total bone marrow cellularity in FeLV-C/Sarma-infected cats, both these cats and the controls exhibited a progressive rise in leukocyte numbers (Table 1), typical of kittens of this age¹². There is therefore a clear selective effect of FeLV-C in ablating the precursors of erythroid cells compared with those of myeloid cells and this effect is reflected in the circulating numbers of end cells of each of these compartments.

Myelofibrosis and medullary osteosclerosis have been described as accompanying features of experimentally produced PRCH¹⁶. These features were also seen in the present experiments which used cloned FeLV-C isolates but the extent and time of development of the conditions displayed considerable individual variation. In the experiment with FeLV-C/Sarma, early histopathological signs of myelofibrosis and osteosclerosis were detectable in the infected cats after 5 weeks but were absent from those examined at 7 weeks. At 11 weeks, cat 10 showed a marked development of both medullary osteosclerosis and myelofibrosis not evident in cat 11. It is apparent, therefore, that the anaemia associated with FeLV-C infection is not due to myelophthisis, as the former can occur in the absence of the myelofibrosis-osteosclerosis complex. It is also unlikely that the osteosclerosis and myelofibrosis are secondary consequences of the anaemia since osteosclerosis is not a feature of feline anaemias induced by other agents.

It is possible that some PRCH cases are associated with FeLV-A or FeLV-AB infections. However, the pronounced association of FeLV-C with anaemia and the ability of all four cloned FeLV-C isolates to induce PRCH suggest that this disease is predominantly associated with this subgroup. Furthermore, none of the FeLV-A or FeLV-B isolates tested in pathogenesis experiments have produced PRCH although other forms of anaemia have been reported. 11,17.

The mechanism of FeLV-C-induced depletion of BFU-E is unknown. It does not appear to be associated with a hyporesponsiveness of BFU-E in infected marrow to erythropoietin as levels of erythropoietin five times above the plateau level do not increase numbers of BFU-E observed (Table 2). The

Colony forming units of erythroid (BFU-E) and myeloid (GM-CFC) precursors per 105 bone marrow cells from normal FeLV-C-infected cats. The haematocrits and total leukocyte counts of cats 1-11 are given in Fig. 1 and Table 1, respectively. Cats 12 and 13 were used in a separate experiment to determine the effect of the erythropoietin (Epo) concentration on BFU-E formation, a different batch of anaemic mouse serum was used in these experiments. The technique used to grow crythroid bursts derived from BFU-E of cat bone marrow was modified from that described for other species²⁴. Femoral bone marrow cells suspended in alpha medium (Gibco) plus 2% fetal calf serum (FCS) were cultured in alpha medium containing nucleosides supplemented with 20% FCS (Flow), 10^{-7} M sodium selenite, 3.4×10^{-6} M human transferrin saturated with iron, 10^{-4} M thioglycerol and 1% bovine serum albumin (BSA) in 0.8% 4000 CPS methylcellulose (Dow Chemicals) The source of erythropoletin was anaemic mouse serum (AMS)²⁵ previously titrated against the International Erythropoletin Standard previously titrated against the International Erythropoietin Standard B The optimum dose for the burst assay in cats 1-11 was 0 4 U Epo per ml of culture. Four aliquots (0 25 ml) each containing $2.5-5.0\times10^4$ cells were plated in wells and incubated at 37 °C in a water-saturated atmosphere of air with 5% CO₂ for 9 days, previously shown to be optimum for the full growth of bursts A more detailed description of the technique will be reported elsewhere. Colonies of granulocytes and macrophages, derived from their progenitors, GM-CFC, were scored in the same cultures used to determine the numbers of bursts. Previous experiments showed that normal mouse serum or AMS provide an adequate stimulus for the growth of GM-CFC In these experiments, the amount of AMS used in the erythroid cultures also provided maximum stimulation for the assay of GM-CFC.

^{*} Cat removed with a haematocrit of 0.092.

decrease in BFU-E may be due to immune elimination of infected cells, to an effect on accessory cells required for erythropoiesis, or a direct block of differentiation of early erythroid precursors. Certain of the adult cases of pure red cell aplasia in man have been postulated to be an autoimmune condition mediated by antibody directed against either erythropoietin or erythroid precursors ^{18,19}. Immune elimination of infected precursors in the cat, following viral antigen expression on the surface of infected cells, seems unlikely. This follows from an examination of bone marrow smears for the presence of FeLV group-specific antigen, p30, by the indirect immunoperoxidase technique, which indicated that widespread infection of myeloid cells occurred but the incidence of GM-CFC (Table 2) and the numbers of circulating leukocytes were normal (Table 1). Furthermore, elimination of infected cells is associated with the production of neutralizing antibody and with the consequent abrogation of the infection, while the establishment of clinical anaemia is associated with a persistent infection and the absence of neutralizing antibody. Lymphoid cell infiltrations have been observed in the marrow of humans having pure red cell aplasia 19 and a lymphoid-dependent suppression of haematopoiesis has been suggested for some cases of aplastic anaemia²⁰. In the FeLV-C-infected cats, however, we did not detect any extensive lymphoid infiltration of the marrow. An effect of FeLV-C on accessory cells cannot be excluded. These cells could either represent cells forming the local microenvironment of the bone marrow or T cells which may promote erythropoiesis²¹. In our experiments a gross effect on the T-cell compartment was noted in cat 11 which had an extensive thymic atrophy, while the other FeLV-C infected cats showed no thymic depletion. In other FeLV-C experiments^{8,10} thymic atrophy has been a major finding, but FeLV of other subgroups induce this change without producing anaemia. However, a more subtle modulation of T-cell subsets may have occurred in the FeLV-C-infected cats which affected their capacity to promote or inhibit erythropoiesis.

Any hypothesis explaining the findings presented here must account for the remarkable selective effect of FeLV-C in producing a red cell hypoplasia but with normal levels of GM-CFC and circulating leukocytes. An effect of FeLV-C on the accessory cells required for erythropoiesis could be consistent with these observations but may also be explained by a mechanism that involves a direct effect of the virus on early erythroid precursor cells. The latter hypothesis is consistent with the subgroup specificity of the disease as the envelope glycoprotein, gp70, is involved both in defining the subgroup of the virus and acting as a binding protein for target cells. Unlike leukaemia and lymphosarcoma, which have latent periods of months or years, erythroid hypoplasia develops rapidly after productive infection. In FeLV-induced immunosuppression develops rapidly after infection, it has been shown that an isolated viral protein can produce many of the effects associated with this syndrome, including the suppression of lymphocyte mitogenesis²². Thus it is important to determine whether the induction of this disease is dependent on integration of the FeLV-C genome into target cells or whether the binding of viral proteins may suppress the activity of erythroid precursor or accessory cells.

We thank Margaret Booth and Mathew Golder for technical assistance. This work was supported by the CRC and the Leukaemia Research Fund.

Two genetic loci control the murine immune response to A-gliadin, a wheat protein that activates coeliac sprue

Martin F. Kagnoff

Department of Medicine, University of California at San Diego. La Jolla, California 92093, USA

Coeliac sprue is a disease in humans that is characterized by small intestinal mucosal injury and malabsorption. Ingestion of dietary gluten by susceptible individuals results in damage to the small intestine. The gliadin fractions of wheat gluten and similar proteins in rye and barley are known to activate the disease process¹. The major histocompatibility complex (MHC) alleles HLA-B8, Dw3 and DRw3 occur at a high frequency in coellac sprue²⁻⁵, suggesting that immunoregulatory mechanisms may be important in the pathogenesis of the disease. We recently reported that murine antibody responses to A-gliadin, a well characterized protein known to activate coeliac sprue1.6 are regulated by genes that map to H-2, the murine MHC10. However, it appeared that an additional genetic locus also might be important in regulating the immune response to gliadin proteins. We show here that two separate genetic regions determine the murine antibody response to A-gliadin: H-2 on chromosome 17 and the immunoglobulin heavy chain (C_H) allotype locus (Igh) on chromosome 12. Possible ways in which these two loci could determine the response against A-gliadin are discussed.

Our studies took advantage of C_H and H-2 congeneic strains of mice to assess the IgG humoral antibody response to Agliadin. Mice bearing the $H-2^d$ haplotype are high responders to A-gliadin whereas those bearing the $H-2^k$, $H-2^j$, $H-2^b$ and H-24 haplotypes are low responders10. Groups of age- and sex-matched mice were injected intraperitoneally (i.p.) with 25 µg A-gliadin in complete Freund's adjuvant (CFA), and bled 18, 29 and 42 days after immunization. IgG anti-A-gliadin antibody levels were measured by radioimmunoassay10

BALB/c $(H-2^d, Igh^a)$ and C.B20 $(H-2^d, Igh^b)$ congeneic mice have different Igh haplotypes but share the same H-2 and background genes. As shown in Fig. 1, IgG anti-A-gliadin responses in C.B20 mice were significantly lower than the BALB/c controls. Similarly reduced anti-A-gliadin responses were seen in the BALB/c Igh congeneic C.AL20 strain (H-2^d Igh^d). The C.B20.B and C.B20 congeneic strains differ only at ~ H-2 whereas the C.B20.B and BALB/c congeneic strains differ both at H-2 and the C_H locus. As shown in Fig. 1, anti-A-gliadin responses in C.B20.B mice were significantly lower than in C.B20 and BALB/c mice.

Figure 2 compares the IgG anti-A-gliadin response in selected inbred murine strains and shows that responses in BALB/c allotype congeneic mice (C.AL20, C.B20) were >50% lower

than in the BALB/c strain. C.B20 $(H-2^a, Igh^b)$ and B10.D2 $(H-2^d, Igh^b)$ mice that share the same H-2 and Igh haplotypes, but differ markedly in background genes, responded similarly. Further, responses in C.B20.B $(H-2^b, Igh^b)$, C57BL/6 $(H-2^b, Igh^b)$ and C57BL/10 $(H-2^b, Igh^b)$ mice that share the same H-2 and Igh haplotypes were similar despite the presence of different background genes (Fig. 2).

different background genes (Fig. 2).

The BALB.B $(H-2^b, Igh^a)$ congeneic strain bears the $H-2^b$ low responder haplotype but has the BALB/c Igh^a haplotype and background genes. BALB.B mice produced significantly greater IgG anti-A-gliadin responses than other $H-2^b$ strains not bearing the Igh^a haplotype. In contrast, mice with the $H-2^b$ haplotype were low responders regardless of the Igh haplotype. Finally, BAB/14 mice $(H-2^d, Igh^{b/a})$ bear the Igh^b allotype markers of the C.B20 and C57BL strain but have some of the immunoglobulin heavy chain variable region (V_H) genes of BALB/c. BAB/14, C.B20 and BALB/c Igh congeneic mice have the same H-2 and background genes. As shown in Fig. 2, BAB/14 anti-A-gliadin responses were significantly lower than those in BALB/c mice.

These data demonstrate that genes at or closely linked to the murine C_H locus have a major role in determining the magnitude of the IgG response to A-gliadin. Thus, we have now shown two separate genetic regions that are associated with regulation of the anti-A-gliadin response—the major histocompatibility complex (H-2) on chromosome 17^{10} and the C_H locus on chromosome 12. Background genes did not significantly influence the anti-A-gliadin response in the strain combinations tested.

Anti-A-gliadin responses varied two- to threefold between H-2 identical strains bearing different Igh haplotypes. However, all $H-2^d$ strains produced significant levels of IgG anti-A-gliadin antibody irrespective of Igh haplotype, and $H-2^k$ strains behaved as low responders regardless of whether or not they bore the Igh^a haplotype. These results suggest that H-2-linked genes predominate in determining the response status to A-gliadin. Within H-2, genes mapping to the I-A subregion seem to be most important in regulating specific anti-A-gliadin responses (M.F.K., unpublished data). Products coded for by H-2- and C_H -linked genes may function independently or interact in controlling the anti-A-gliadin response.

Our data do not distinguish whether control of the anti-A-gliadin response is mediated by C_H genes or genes closely linked to that locus. Structural genes closely linked to the C_H locus are known to encode variable region idiotypic determinants on immunoglobulin heavy chains $(V_H \text{ genes})^{11-13}$. Such idiotypic

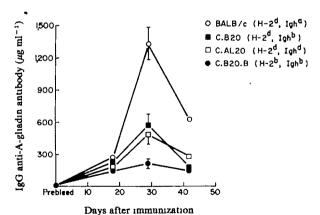

Fig. 1 IgG anti-A-gliadin responses in BALB/c allotype congeneic mice. A representative experiment is shown in which groups of four to six 10-week-old female mice were immunized with 25 μ g A-gliadin i.p. in CFA. Prebleed sera and sera obtained from individual mice on days 18, 29 and 42 after immunization were assayed for specific IgG anti-A-gliadin antibody by radioimmunoassay. Vertical bars represent s.e.m. On day 29, C.B20, C.AL20 and C.B20.B responses were significantly less (P < 0.001) than BALB/c responses, and C.B20.B responses were significantly lower than the C B20 responses (P < 0.01).

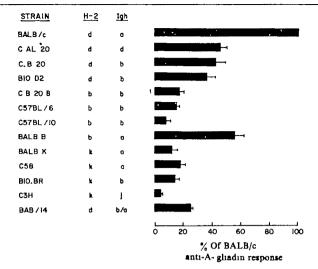

Fig. 2 Comparison of IgG anti-A-gliadin responses in inbred strains of mice. Groups of 4-12 mice of each strain were immunized with 25 μ g A-gliadin i.p. in CFA. Results compare day 29 IgG anti-A-gliadin responses in various strains with the responses in age- and sex-matched BALB/c mice that were immunized and assayed in parallel. In all strains responses on day 29 were greater than those on days 18 or 42. Anti-A-gliadin antibody was not detected in prebleed sera from any of these strains. Horizontal error bars represent s.e.m. Responses in C3H/An and C3H/St mice were the same (not shown). However, IgG anti-A-gliadin responses were 10-fold greater in C3H.OH than in either C3H strain. The C3H.OH recombinant strain is congeneic to C3H but bears the H- 2^d haplotype at K and in the I region of H-2.

determinants might regulate the anti-A-gliadin response through their involvement in lymphocyte receptor recognition of A-gliadin determinants or cellular cooperation. For example, it could be postulated that T-cell help for the IgG anti-A-gliadin response is directed to V_H -coded idiotypic determinants $^{14-18}$ on anti-A-gliadin antibody associated with the B cell. This interpretation predicts a unique pattern of idiotype expression to A-gliadin determinants among strains of mice bearing different immunoglobulin heavy chain allotypes. Alternatively, CH genes would seem to control the anti-A-gliadin response if allotype-specific T-cell help or suppression 19,20 differs among the various Igh haplotypes. However, T regulatory cells that appear to be allotype specific might be idiotype rather than allotype specific due to a close linkage and nonrandom association between C_H and V_H products²¹. Minor histocompatibility genes that are closely linked to the C_H locus²²⁻²⁴ might control the anti-Agliadin response by coding for lymphocyte cell-surface structures that are important in the recognition or binding of A-gliadin determinants, or in cellular cooperation. Finally, C_H-linked genes postulated to code for the constant regions of T-cell receptors on helper and suppressor cells25 may be important in the regulation of the anti-A-gliadin response.

To determine whether V_H genes regulate the anti-A-gliadin response, we used BAB/14 $(H-2^d, Igh^{b/a})$ mice. BAB/14 is an intra-V-region recombinant strain that bears the C_H genes of C.B20 and C57BL (that is, Igh^b) but expresses many of the V-region idiotypic markers of the BALB/c strain^{26,27}. The finding that IgG anti-A-gliadin responses in BAB/14 mice were significantly lower than in BALB/c mice could argue against V_H structural gene control of the anti-A-gliadin response. On the other hand, it is known that the BAB/14 strain expresses some C57BL idiotypes and fails to express certain BALB/c idiotypes^{26,27}. Thus, the BAB/14 data may suggest that the V_H structural genes determining the putative BALB/c A-gliadin idiotype map closer to the C_H allotype locus than to the V_H genes that determine the BALB/c idiotype to determinants like $\alpha(1,3)$ linkages on dextran B1355^{13,28}. Alternatively, differences in the anti-A-gliadin response between BAB/14 and BALB/c mice might reflect an allotype-linked regulatory

gene that controls the phenotypic expression of the putative anti-A-gliadin idiotype.

Coeliac sprue is unique among the HLA-associated diseases in that the proteins known to activate this disease are well characterized^{1,6-9}. Although more than 80% of patients in certain populations with coeliac sprue have the HLA-B8. Dw3 and DRw3 alleles2-5, many individuals with these same HLA alleles ingest dietary gluten and do not develop disease. Further, family studies indicate that HLA-identical siblings are often disparate for the development of coeliac sprue5,29. Such

observations have led to the suggestion that a second genetic region may be important in the pathogenesis of this disease³⁰ Our studies with A-gliadin in mice suggest that the second genetic locus may be linked to the genes that code for immunoglobulin heavy chain allotype. Our preliminary studies in man indicate that this is indeed the case.

Radical scavenging and stimulation of prostaglandin synthesis not anti-inflammatory?

T. G. Payne, B. Dewald, H. Siegl, H. U. Gubler, H. Ott & M. Baggiolini

Preclinical Research, Sandoz Ltd, CH-4002 Basle, Switzerland

Prostaglandins (PGs) are produced from arachidonic acid by a cascade of enzymes, the initial step being the conversion of arachidonic acid to PGG2 by cyclooxygenase. In the next step, PGG₂ is converted to PGH₂, and it is at this stage that an oxidative radical is generated, presumably OH, which is capable of inactivating several enzymes of the arachidonic acid cascade^{1,2}. This inactivation can be prevented by radical scavengers. MK 447, a phenolic compound with such properties, was indeed found to facilitate the conversion of PGG2 to PGH₂ and therefore to enhance PGE₂ synthesis^{2,3}. MK447 also inhibits irritant-induced inflammation in mice and rats; this was thought to depend on radical scavenging, which led Kuehl and colleagues to suggest that PGG2 and OH are mediators of inflammation^{2,3}. We have tested MK447 analogues containing asymmetric centres and report here that although both antipodes were equipotent radical scavengers and stimulators of prostaglandin synthesis, only the (+) antipodes had anti-inflammatory and diuretic⁴ properties. This indicates that the radical scavenging properties and pharmacological actions of MK 447 and derivatives are not interdependent and questions the pro-inflammatory role of PGG₂.

Several analogues of MK 447 were prepared and tested in a cell-free system for enhancement of prostaglandin synthesis from arachidonic acid, and in the rat for inhibition of irritantinduced paw oedema and for diuretic activity. We present here data for MK 447 and two analogues, A and B, which contain an asymmetric carbon atom (Fig. 1). Compounds A and B were resolved into their optical antipodes by crystallization of the dibenzoyl tartaric acid and tartaric acid salts, respectively, the details of which will be reported elsewhere (H.O., in preparation). The compounds were tested both as racemates and as the pure isomers.

We tested the effect of the aminophenols on the formation of PGE₂ from arachidonate by a microsomal preparation from bovine seminal vesicles. In both the presence and absence of

Table 1 Effects of MK 447 and related phenolic compounds on PGE₂ formation by bovine seminal vesicle cyclooxygenase

		Relative amounts of PGE ₂ formed		
Compound	Conc. (µM)	-GSH	+1 mM GSH	
None		100	100	
MK 447	10	159	149	
	100	323	211	
A (racemic)	10	158	148	
	100	405	236	
A (+) isomer	10	170	152	
	100	404	245	
$A^{(-)}$ isomer	10	158	152	
	100	412	223	
B (racemic)	10	187	143	
	100	391	229	
B(+) isomer	10	168	143	
	100	362	228	
$\mathbf{B}(-)$ isomer	10	184	` 144	
	100	388	241	

Bovine seminal vesicle microsomes (1.85 mg protein), prepared by the method of Takeguchi et al. 9 , were incubated with [1-Carachidonic acid (33 nmol, corresponding to 0.04 µCi) in 1 ml of 0.1 M sodium phosphate buffer pH 7.4, in the presence or absence of GSH and the indicated concentrations of test substances. After 30 min at 37 °C, the reaction was terminated by acidification to pH 4. Products and non-metabolized arachidonic acid were extracted into ethyl acetate, separated by TLC (benzene/dioxane/acetic acid = 50:50:2), eluted and measured by scintillation counting. The data are presented as percentage of controls. In control assays, PGE2 production was 217 and 1,182 ng per mg of protein per 30 min, in the absence and presence of 1 mM GSH, respectively.

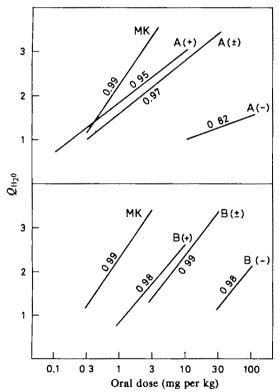

reduced glutathione (GSH), all compounds stimulated strongly the formation of PGE₂ (Table 1) and PGF₂ (not shown) in a concentration-dependent manner. However, in the presence of GSH, which by itself stimulates PGE₂ formation⁵, the enhancement by the phenolic compounds was reduced. Independent of their structure and chirality, all compounds tested showed similar effects. The same results were obtained for various other phenolic compounds (data not shown). In agreement with Kuehl et al.3, the structural determinants essential for activity were found to be the phenolic hydroxyl group and an adjacent aminomethyl substituent.

The anti-oedematous and diuretic effects of MK 447 and compounds A and B are summarized in Table 2. MK 447 and

Fig. 1 Structure of MK 447 and the two optically active derivatives, compounds A and B.

both racemates of the two analogues showed moderate to strong inhibition of the inflammatory response induced by intraplantar injection of carrageenin, and markedly enhanced water and sodium excretion. Despite their close structural relationship and almost identical stimulation of prostaglandin synthesis, compounds A and B were only about one third and one tenth, respectively, as active as MK 447 in inhibiting paw oedema and enhancing diuresis. Most remarkably, both in vivo activities appeared to be due to the (+) isomer. As shown in Fig. 2, the (-) isomers are both much less effective than the (+)isomers or the racemates.

Comparison of the pharmacological activities of the two isomers is only valid if their absorption and fate in vivo are similar. This was tested in the case of compound B. The (+) and (-) antipodes were administered orally to separate groups of rats at a dose of 10 mg per kg, and urine was collected during the following 7 hours. In analogy with MK 447 (ref. 6), Osulphate was expected to be the major urine metabolite. The urine was desalted using Sep-pak cartridges (Waters Associates, Massachusetts) and incubated at 55 °C for 2 h with Helix pomatia extract (100,000 Fishman units of β -glucuronidase and 10° Roi units of arylsulphatase). The samples were then evaporated to dryness, taken up in a small volume of ethanol

r(

Fig. 2 Dose-dependent diuretic effect of MK 447 and related phenolic compounds in the rat (for method see Table 2), expressed as the ratio of water excretion in the treated compared with that in control animals, $Q_{\rm H2O}$. The curves were calculated by regression analysis of the values obtained for individual animals; the correlation coefficient, r, is shown for each curve. Each compound was tested at 3-5 doses in 3-4 animals per dose. MK, MK 447.

Table 2 Anti-oedematous and diuretic activities of MK 447 and related phenolic compounds in the rat

	Inhibition of carrageenin and naphthoylheparamine-induced paw oedema (ED 50; mg per kg p.o.)		Diureti in th (ED ₁₀₀ ; mg Water	e rat
Compound	C C	NH	excretion	excretion
MK 447	3.9	2.8	0.7	0.75
A (racemic)	10.6	13.2	2.0	1.5
A (+) isomer	6.5	8.2	1.1	1.1
A (-) isomer	>30.0	>30.0	>100.0	>100.0
B (racemic)	12.2	14.2	6.5	7.3
B(+) isomer	4.3	4.0	4.6	4.5
B(-) isomer	>30.0	>30.0	85.0	>100.0

The carrageenin (C) oedema test 10 and the naphthoylheparamine (NH) oedema test¹¹ were performed in the rat according to established methods. In both cases, paw swelling was assessed by conductometry as described by Kemper and Ameln¹². The compounds were given orally (p.o.) as a suspension in saline containing 0.5% tragacanth, 1 h before local injection of the irritant. The ED₅₀ (the average dose giving 50% inhibition of irritant-induced swelling compared with untreated controls) was determined from dose-response curves (3-4 doses per compound, 5 rats per dose). The inhibition of swelling after a dose of 30 mg per kg of the (-) isomers was 15 and 2% for compound A and 19 and 7% for compound B. Diuretic activity was assessed by the method of Flückiger et al. 13. Fasted rats (200 g) were hydrated (30 ml water per kg, orally) and 2 h later, after emptying the bladder, they were given the test compounds in 50 ml of isotonic saline per kg. The total urine produced during the following 3 h was measured and tested for sodium, potassium and chloride content. Average water and sodium excretion per 200 g body weight was calculated (3-4 rats per dose) and the ED₁₀₀, the average dose inducing a 100% increase in both values, determined for 3-5 different dosages.

and analysed by TLC. Three solvent systems were used and the compounds were detected under UV light and with iodine vapours. Similar amounts of the aminophenol were obtained after administration of either antipode, indicating that they were absorbed and excreted to the same extent. In both cases, no aminophenol was detectable in urine samples which were not treated with the hydrolases, suggesting that the metabolism of the two antipodes was similar.

Our results show that the anti-oedematous effects of phenols like MK 447 and its analogues are unlikely to depend on the ability of the compounds to scavenge oxygen radicals and hence to increase the conversion of PGG₂ to PGH₂ and further metabolites. The two optical isomers of compounds A and B enhance prostaglandin synthesis to the same extent. As indicated by the experiments with compound B, both isomers have similar absorption and fate in rats. Nevertheless, they differ widely in their in vivo activities, the (+) isomers only being biologically comparable to MK 447. These results suggest that the theory that radicals which arise from the peroxidase-dependent reduction of PGG₂ are pro-inflammatory and that PGG₂ is a key element in the pathogenesis of inflammation^{2,3,7} needs revision.

Our results also question the notion that the main action of MK 447, that is, diuresis and saluresis⁴, is mediated by its enhancing prostaglandin synthesis. This was suggested by the observation that MK 447-induced diuresis was inhibited by indomethacin^{4,8}. However, as the (-) isomers of compounds A and B also have some diuretic activity, it cannot be ruled out entirely that an increase of prostaglandin production may contribute to the overall effect.

A model of the nerve impulse using two first-order differential equations

J. L. Hindmarsh & R. M. Rose

Department of Applied Mathematics and Astronomy and Department of Physiology, University College, Cardiff, Cardiff CF1 1XL, UK

The Hodgkin-Huxley model of the nerve impulse consists of four coupled nonlinear differential equations, six functions and seven constants. Because of the complexity of these equations and the necessity for numerical solution, it is difficult to use them in simulations of interactions in small neural networks. Thus, it would be useful to have a second-order differential equation which predicted correctly properties such as the frequency-current relationship. Fitzhugh² introduced a secondorder model of the nerve impulse, but his equations predict an action potential duration which is similar to the inter-spike interval3 and they do not give a reasonable frequency-current relationship. To develop a second-order model having few parameters but which does not have these disadvantages, we have generalized the second-order Fltzhugh equations2, and based the form of the functions in the new equations on voltageclamp data obtained from a snall neurone. We report here an unexpected property of the resulting equations—the x and y null clines in the phase plane lie close together when the phase point is on the recovery side of the phase plane. The resulting slow movement along the phase path gives a long inter-spike interval, a property not shown clearly by previous models² The model also predicts the linearity of the frequency-current relationship, and may be useful for studying detailed interactions in networks containing small numbers of neurones.

Although our model may be seen as a generalization of the Fitzhugh equations², it can be developed from first principles if it is assumed that the rate of change of membrane potential depends linearly on z (the current passed through the electrode), and y (an intrinsic current), and depends nonlinearly on membrane potential, giving

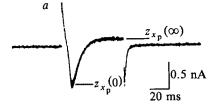

$$\dot{x} = -a(f(x) - y - z) \tag{1}$$

We assume also that the rate of change of intrinsic current is given by

$$\dot{y} = b(g(x) - y) \tag{2}$$

In these equations, a and b are constants, and equation (2) has a form which ensures that the time course of z in voltage-clamp conditions is exponential (see equation (4)). This is a simplification which ignores the voltage-dependence of the time

To determine the form of f(x) and g(x) in equations (1) and (2), a large cell from the visceral ganglion of the pond snail, Lymnaea siagnalis, was clamped to a range of different voltages (x_p) , and the initial $(z_{x_p}(0))$ and steady-state $(z_{x_p}(\infty))$ values of the clamping current were measured, giving a conventional⁵ current-voltage plot (Fig. 1). As the cell fires repetitively in the resting state, the membrane potential was biased initially by adjusting z so that the cell just stopped firing. This corresponds to an artificial stable equilibrium point, and will be used as the origin (x = 0, y = 0) in the phase plane. In the current-voltage plot (Fig. 1), the scale is also positioned so that the current required to maintain the equilibrium voltage is at the origin

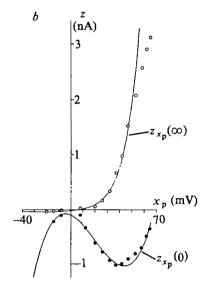

Fig. 1 Voltage-clamp data on which the model is based. In these experiments, the brain of the pond snail L. stagnalis was pinned out in a chamber with a sylgard base, and the outer sheath softened using pronase enzyme for a few minutes before recording. The bathing solution had the following composition (mM): Na⁺, 24.0; K^+ , 2.0; Ca^{2+} , 4.0; Mg^{2+} , 2.0; Cl^- , 38.0; $H_2PO_4^{2-}$, 0.1; Na-HEPES, 35.4. A large cell (~200 μ m) in the visceral ganglion was impaled with a bevelled glass microelectrode filled with 3 M KCl, and having a resistance of 4-5 MΩ. The cell was clamped using the single-electrode voltage-clamp technique of Wilson and Goldner', a. Current change recorded for a voltage step (x_n) of 25 mV from the equilibrium point (cell held at an actual potential of -60 mV, which is the equilibrium point, x = 0, in the measurements). The initial $(z_{xp}(0)$, or peak inward) and final $(z_{xp}(\infty)$, or steady-state outward) currents are indicated, the final currents being measured after 60 ms in this case. b, Initial and final currents obtained from records such as shown in a are plotted for different values of clamp potential (x_p) measured from the equilibrium point. Negative values of z are inward, and positive values are outward currents. Final currents were measured 100 ms after onset of voltage step. Different animal than in a, but curves are typical for this cell (experiment repeated five times). The $z_{xp}(0)$ points have been fitted by the least-squares method, using the cubic equation $f(x) = cx^3 + dx^2 + ex + h$, where c = 0.0001, d = 0.001, e = 0.01 and h = 0.1. The $z_{x_p}(\infty)$ points were fitted by an exponential of the form $g(x) = q e^{rx} - s$, where q = 0.024, r = 0.088 and s = 0.046.

(z=0). Therefore, at the equilibrium position $x=y=\dot{x}=\dot{y}=$ z = 0. The time course of the current, after the onset of a step in voltage to x_p , is given (from equation (1) with $\dot{x} = 0$) by

$$z_{x_p}(t) = f(x_p) - y(t) \tag{3}$$

where y satisfies equation (2) with $x = x_p$. Therefore, $z_{x_0}(t)$ is given by

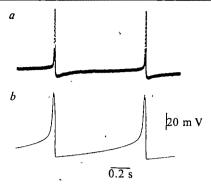

$$z_{x_0}(t) = f(x_0) - g(x_0)(1 - e^{-bt})$$
 (4)

and hence

$$z_{x_p}(0) = f(x_p), \text{ and } z_{x_p}(\infty) = f(x_p) - g(x_p)$$
 (5)

To obtain $f(x_0)$, the values of the initial currents $(z_{r_0}(0); \text{ Fig.})$ 1b) were fitted by a cubic equation. To obtain $g(x_p)$, an exponential function was fitted to the value of the final currents $(z_{xx}(\infty))$; Fig. 1b), and $g(x_p)$ was obtained from equation (5). The time constant b was estimated from voltage-clamp current records

Fig. 2 Comparison between a, actual and b. calculated waveforms for the same cell as in Fig. 1b. The calculated waveform is the solution to equations (7) and (8) for a current of z =0.008, with the constants $a = 5,400 \text{ mV s}^{-1}$ nA^{-1} , $b = 30 \text{ s}^{-1}$ and and using the functions f(x)and g(x) shown in Fig. 1b. Numerical solutions were obtained using the

Runge-Kutta-Merson method⁸ with variable step length. In these calculations we found that repetitive firing occurred down to z=-0.026 rather than z=0 as expected (procedure outlined in the text). This was due to the approximations adopted, which slightly changed the values of f(x) and g(x) at the origin. As the computed equilibrium point is at z=0.034 (=0.008±0.026) in Fig. 4. The recorded action potentials were obtained in current-clamp conditions with an experimental z value of 0.04 and were photographed ~ 1 min after imposing the current step.

(Fig. 1a), which were assumed to follow an exponential time course, and the time constant a was obtained by applying a current step to the system at rest in the equilibrium position (0,0). If the step in current is $z(t) = z_p$ for $t \ge 0$ then a may be obtained from the slope of the voltage change immediately after the onset of the current-clamp step. This is given by equation (1) with f(0) = 0 and y(0) = 0:

$$\dot{x}(0) = az_{p} \tag{6}$$

Thus the assumed form for our equations is

$$\dot{\mathbf{x}} = -a(f(\mathbf{x}) - \mathbf{y} - \mathbf{z}) \tag{7}$$

$$\dot{y} = b(f(x) - q e^{rx} + s - y) \tag{8}$$

where $f(x) = cx^3 + dx^2 + ex + h$, and a-h, q, r and s are constants. After measuring a and b, and fitting cubic and exponential functions to the $z_{x_p}(0)$ and $z_{x_p}(\infty)$ data of Fig. 1b, the solutions of equations (7) and (8) were obtained by numerical integration.

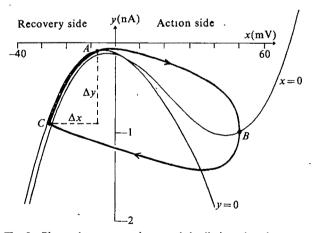

Fig. 3 Phase plane representation of the limit cycle solution to equations (7) and (8). The values of the constants are the same as in Fig. 2, except that a z value of 0.033 has been used so that the equilibrium point can be more clearly distinguished. The x=0 curve has been displaced horizontally to the right by 2-3 mV so that the separation between the x and y null clines on the recovery side of the diagram can be seen more easily. The x=0 curve is similar to that of Fitzhugh², but the y=0 curve bends round to follow the x=0 curve in the lower left-hand quadrant, which is significantly different from the Fitzhugh model. The limit cycle is divided into an action potential phase $(A \to B \to C)$ and a recovery phase $(C \to A)$, during which the phase point moves slowly between the x and y null clines. The differences Δx and Δy are, respectively, the changes in membrane potential and intrinsic current during recovery.

Figure 2 compares the calculated x(t) waveform with that recorded from the cell. The model clearly predicts a ratio of spike duration to inter-spike interval which is similar to that actually recorded, although the calculated action potential is of rather longer duration than the recorded spike; the pacemaker potential also rises to a higher threshold in the model. Some of these differences may be corrected by taking into account the voltage dependency of the time constants, but these modifications are not introduced here because they detract from the simplicity of the model.

Although this model is not as accurate as more complicated models of repetitive firing⁶, it has a conceptual advantage which becomes apparent when the oscillation is plotted onto the phase plane. The main difference between this model and that of Fitzhugh² is the introduction of g(x) into the equation for \dot{y} . By using the phase diagram (Fig. 3) it becomes easy to understand why this modification is so important in lengthening the recovery phase between successive action potentials. In the phase plane, when the limit cycle crosses the $\dot{x} = 0$ curve at C (Fig. 3), it is constrained to move along the narrow path between the $\dot{x} = 0$ and $\dot{y} = 0$ curves. Because the phase path is so close to both the x and y null clines, progress along the limit cycle will be much slower from C to A (the pacemaker or recovery phase) than from A through B to C (the action potential part of the cycle). By contrast, in Fitzhugh's model the $\dot{x} = 0$ and $\dot{y} = 0$ curves diverge markedly on both sides of the diagram, so that x and y change almost as rapidly during the pacemaker phase as during the spike itself.

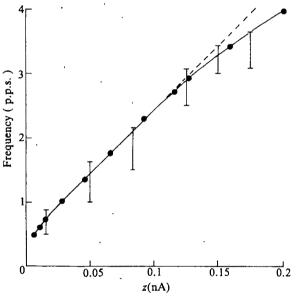

Fig. 4 Comparison of the calculated and experimental frequency-current relationship (pulses per second). The calculated frequencies () were derived from numerical integration of equations (7) and (8) using the same parameter values as in Fig. 2 but with different values of z Calculated frequencies are plotted relative to the computed equilibrium point (z = -0.026; see Fig. 2). Experimental z values were measured relative to the experimental equilibrium point (at which z=0; there were no action potentials). Over most of the range there is a linear relationship between frequency and applied current, with both experimental and calculated curves having a similar slope. At higher values of z, the calculated curve and the experimental points begin to approach a limiting frequency at a similar z value, although the experimental points appear to fall off more sharply from linearity (broken line) than the theoretical prediction. This particular cell also shows adaptation of firing frequency to an applied current step, so that the values for the experimental frequencies lie within the upper (-initial frequency in response to step) and lower (=final frequency) limits of the bar lines. Thus a precise comparison cannot be made because the model has not yet been modified to include adaptation. Experimental points were obtained from a different animal than that used in Fig. 1b, but the experiment was repeated four times and gave consistent results.

Numerical solution may also be used to predict the frequency-current relationship. The computed values of the frequency are linearly related to the current (Fig. 4) and compare reasonably well with the experimental values. It is also possible to derive an expression for the frequency-current relationship fairly simply. From equations (1) and (2) we see that

$$b\dot{x} + a\dot{y} = ab(g(x) - f(x)) + abz \tag{9}$$

Then the expression g(x)-f(x) (= $-z(\infty)$; equation (5)) may be approximated for x < 0 by a small positive constant M (see $z_x(\infty)$ in Fig. 1b). Integrating (9) we obtain

$$b\Delta x + a\Delta y = abMT + abzT \tag{10}$$

where Δx and Δy are the changes in the values of x and y during recovery (from C to A in Fig. 3), which occurs in time T, say. If we ignore the spike duration, the frequency f of oscillation is given by

$$f = \frac{1}{T} = \frac{ab(z+M)}{b\Delta x + a\Delta y} \tag{11}$$

from which we can see that, to the extent that Δx and Δy are independent of z, f is linearly related to z (see Fig. 4).

The model therefore predicts the frequency-current relationship as well as giving a reasonably accurate representation of the time course of the membrane potential change. It also provides a simple explanation of why the recovery time is much longer than the spike duration. Because these equations are simpler to understand than the four-dimensional Hodgkin-Huxley equations¹, and can be solved numerically in a shorter time, they may be useful in studying small neural networks.

We thank Dr W. A. Wilson for supplying us with further information on the single electrode voltage-clamp, and Mr W. L. Barry and Mr T. Ford for constructing the voltage-clamp apparatus.

Induction of helical liposomes by Ca²⁺-mediated intermembrane binding

Ke-Chun Lin*, Robert M. Weis & Harden M. McConnell

Stauffer Laboratory for Physical Chemistry, Stanford University, Stanford, California 94305, USA

Extensive freeze-fracture electron microscopic studies of Ca2+containing mixtures of an acidic phospholipid (cardiolipin) and phosphatidylcholines¹⁻⁵, have revealed certain replica features which have been interpreted as regions of membranemembrane attachment³⁻⁵. Spin-label paramagnetic resonance spectra of mixtures of another acidic phospholipid (phosphatidylserine) and phosphatidylcholines have provided evidence for Ca2+-mediated lateral phase separations of the acidic phospholipids⁶⁻⁸, and their involvement in intermembrane binding⁷. We report here that in the presence of Ca²⁺ binary mixtures of cardiolipin and phosphatidylcholines readily form tightly folded single- and double-helical liposomes; we invoke membrane-membrane attachment to explain this phenomenon.

Ethanolic solutions of bovine heart cardiolipin (Ca²⁺-free: Sigma) and dimyristovlphosphatidylcholine (Sigma) were evaporated to dryness to form binary mixtures containing 37 mol % cardiolipin (1.7 mg total lipid). The lipid was dissolved in chloroform/methanol (10:1 v/v) and evaporated to dryness, then 160 µl phosphate-buffered saline (PBS) were added with or without 2 mM EDTA and the mixture was incubated at 45 °C for 5 min, vortexed for 10-15 s, then diluted 20-fold with PBS. All experiments were carried out at 25-26 °C. well above the chain-melting transition of dimyristoylphosphatidylcholine (23 °C).

We used two experimental protocols: (1) after addition of PBS+EDTA and vortexing, the dilution with PBS contained no Ca²⁺. The sample was placed on a microscope slide with an elevated coverslip (100 $\mu m)$ and a concentrated CaCl $_2$ solution (0.01-1 M) was added from one side. Ca2+ ions gradually diffused through the solution, allowing observation of helix formation (see Fig. 1a-d). (2) For the mixture incubated without EDTA, the subsequent dilution with PBS contained various low concentrations of Ca^{2+} ($10^{-6}-10^{-3}$ M).

Single and double helix formation, observed using protocol (1), is shown in Fig. 1. Long tubes were often observed in the absence of Ca²⁺, together with liposomes having typical irregular shapes. The presence of regular tubes and irregular liposomes may be explained by possible lipid compound formation and phase separations in binary mixtures of these lipids9. The tubes were almost perfect cylinders, although end defects were frequently seen, and were usually multilamellar but occasionally unilamellar, as judged by microscopic observation of pronounced brownian motion, characteristic of unilamellar liposomes¹⁰. Photobleaching recovery experiments measuring diffusion parallel to the long axis of the tubes yielded lateral diffusion coefficients typical of fluorescent lipid probes ($D \sim$ $10^{-8} \, \text{cm}^2 \, \text{s}^{-1}$).

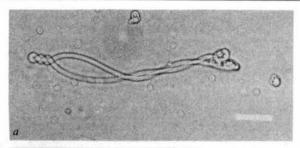

Protocol (1) provided evidence that the rate of helix formation increased with increasing Ca²⁺ concentration. Protocol (2) permitted the determination of the minimum concentration of tion required for helix formation; compared with controls (no Ca²⁺), significantly more helices were formed at Ca²⁺ concentrations as low as 10^{-6} M.

The thermodynamic driving force for helix formation is the Ca2+-mediated membrane-membrane binding. At higher Ca2 concentrations, helices rapidly collapse on themselves forming a variety of more complex structures. It is possible that helices represent kinetic intermediates in the Ca2+-mediated transformation of tubes to more complex structures, as each step of helix formation represents an increase in the area of membranemembrane contact. The formation of a typical single helix is simple; it is initiated at one end, and is smooth and continuous. However, double-helix formation is sometimes complex; it initiates from a hairpin loop and progresses in a stepwise manner. A complete regular double helix with no loose ends can initiate at a hairpin loop but not in the centre of a tube; this requires sliding as well as twisting of one tube relative to the other (see Fig. 1a-c).

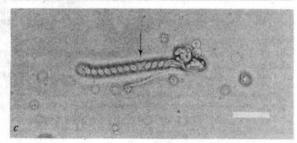

The rate at which helices form in the presence of Ca²⁺ is consistent with earlier proposals concerning Ca2+-mediated lateral phase separations of acidic phospholipids⁶⁻⁸, and with the rates of lateral diffusion of these lipid molecules reported here. Ca²⁺ chelation by phosphate groups should be favoured when these groups have a three-dimensional configuration, rather than a two-dimensional configuration provided by a single membrane.

The forces opposing helix formation are weak. The shear modulus of a fluid membrane is essentially zero; a negligible force is required to twist one region of a lipid tube relative to another. We observed no distortion of the circularity of the tubes, thus there was no detectable volume or surface area change of the tubes on helix formation. Note that the outer diameter of the double helix in Fig. 1 is twice the diameter of the tube. No stretch or compression elastic energy is required to convert a cylindrical tube into a helix because lipids on the

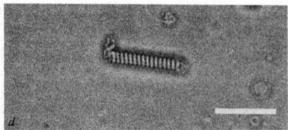

Fig. 1 Helical liposomes derived from binary mixtures containing 37 mol % cardiolipin and 63 mol % dimyristoylphosphatidylcholine as Ca2+ ions diffuse from a 0.01 M CaCl2 solution at the edge of a coverslip into the region where the liposomes are located. a-c Illustrate the formation of a double helix initiated on the left at a hairpin loop, and on the right in an extended region of membrane-membrane contact. In a and b both helices are righthanded. In subsequent photographs (not shown) the helix at the right-hand end became unwound as the helix on the left continued to form. Subsequently, as the right-handed helix to the left continued to form, a left-handed helix formed on the right, and the two helices met in a soliton-like defect indicated by the arrow in c. A single helix is shown in d. Scale bars, 25 µm. The elapsed time from a to c is \sim 5 min; double-helix formation is not continuous but proceeds in a stepwise fashion. A similar length of time was observed for the continuous formation of the single helix shown completed in d.

inside of the helix can flow to the outside on bending. Helfrich¹¹ has estimated the curvature elastic energy for bending a lipid tube (of radius r) so that it has a radius of curvature R: to first-order approximation this is $\pi Kr/2R^2$ per unit length, where K is the curvature elastic modulus. For egg lecithin, $K \simeq$ 23×10^{-12} erg (ref. 11). Assuming one lipid molecule per 10 Å along a contact line between helical tubes, and using the above values of K, we calculate the curvature elastic energy of lipid touching this line to be 0.013n kcal mol⁻¹ for a tube with radius $r = 1 \mu m$ and having n bilayer membranes. Thermal energy, RT, at room temperature is 0.6 kcal mol⁻¹. Clearly, weak membrane-membrane binding energies can overcome curvature elastic energy and stabilize helices.

We acknowledge that Dr Alec Bangham has independently observed the formation of tubular and helical liposomes on

hydration of egg lecithin with saline solution, and we thank him for supplying photographs of these helical liposomes. The double helices of egg lecithin are very similar to those reported here. This work was supported by NSF grant PCM 8021993.

Effects of Duchenne muscular dystrophy on muscle protein synthesis

M. J. Rennie*, R. H. T. Edwards*, D. J. Millward†, S. L. Wolman†, D. Halliday‡ & D. E. Matthews§

The primary defect in Duchenne muscular dystrophy (DMD) is unknown but muscle growth failure and wasting of skeletal muscle must be the result of an imbalance between protein synthesis and degradation, that is, the rate of muscle protein synthesis is insufficient to replace degraded proteins and expand the protein mass. In patients with DMD, excretion of 3-methylhistidine is dramatically increased relative to creatinine and this is commonly accepted as evidence of increased muscle myofibrillar degradation¹⁻³. As rapid wasting of muscle has not been observed to occur in the disease, increased protein degradation ought to be accompanied by increased protein synthesis and this has been observed or implied from measurements in animal models of the disease4-6. However, so far no direct measurements of muscle protein synthesis or degradation have been made in patients. We report here the first direct measurements in vivo of rates of skeletal muscle protein synthesis in patients suffering from DMD. The results, obtained using stable isotope tracers, clearly show that a marked reduction in muscle protein synthesis is the primary cause of the growth failure and that muscle protein degradation cannot be elevated.

We studied seven normal fed adult men aged 22-65 yr and five boys with Duchenne muscular dystrophy, aged 12-18 yr. Three of the patients were wheelchair bound and the two youngest were on the verge of becoming so. Investigations of these subjects using radioactive isotopes would not have been ethically feasible. We infused [1-13C]leucine intravenously after a priming dose, and measured the incorporation of labelled leucine into skeletal muscle proteins in samples obtained by needle biopsy8 (Fig. 1). This approach also allows the measurements of whole-body leucine flux and its components, leucine oxidation and whole-body protein synthesis (Table 1)

The rate of muscle protein synthesis in normal adults was determined from the increase in isotopic enrichment between two biopsies; as synthesis rates calculated from the enrichment observed in a single biopsy taken after 7 h were not significantly different from this estimate, we calculated synthesis rates in patients from the enrichment in a single biopsy sample taken at 7.5 h. The precursor labelling was assumed to be that of the keto acid of leucine, α -ketoisocaproate (α -KIC), in plasma. Most plasma KIC originates from skeletal muscle¹⁰ so that its enrichment should closely reflect that of intracellular leucine in muscle. This was confirmed in four normal adults and three patients by direct measurements of the enrichment of free leucine in the muscle biopsy intracellular water (unpublished results).

In normal adults (Table 1) the rate of muscle protein synthesis was 0.198% h⁻¹, twice the value determined previously¹¹. However, in those studies using ¹⁵N-lysine, the precursor labelling was taken as that of plasma lysine, which we believe gave erroneous results. Studies using infusions of lysine and leucine in pigs have shown that the ratio of intramuscular free lysine labelling relative to plasma is less than 50% of that for leucine ¹², which explains the discrepancy and supports our current measurements. From creatinine excretion as a proportion of muscle mass¹³ and from our measurements of muscle protein content (17%) and leucine content of protein (8%), we estimate that in a man weighing 70 kg, 126 g of protein are synthesized per 12 h in the fed state, that is 53% of the whole-body synthesis rate. This is a higher proportion than that observed in smaller animals¹⁴.

In the patients with DMD, whole-body protein synthesis was depressed as was that in muscle (Table 1), the former being only half that observed in normal adults, and as all dietary leucine was oxidized, no net protein deposition could occur. The rate of muscle protein synthesis measured during feeding

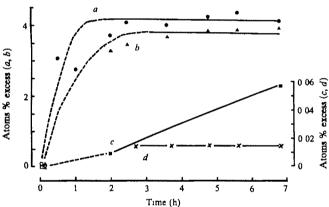

Fig. 1 Enrichment with 13 C of blood leucine (\bullet) and of α -KIC (\blacktriangle) (transamination product of leucine), leucine incorporated into quadriceps muscle protein (a) (obtained by needle biopsy, with local anaesthesia) and of expired CO₂ (x) during the primed (0 8 mg per kg) infusion (1 mg per kg per h) of [1-13C]leucine (KOR Inc., Massachusetts) in a normal healthy adult man (80 kg, 42 yr old). A similar pattern of changes was observed in all subjects. The subject was fed 0.1 g protein and 14 kJ per kg at hourly intervals. Blood was sampled via an indwelling cannula and the enrichment with 13 C of leucine and α -KIC determined by gas chromatography—mass spectrometry^{7,30}. Expired CO₂ was collected in 5-1 Douglas bags attached to a three-way valve and mouthpiece and a portion of the sample immediately transferred to an evacuated glass vial. The enrichment of CO₂ with ¹³C was measured in a VG micromass 602D motope ratio mass spectrometer after drying and trapping of solid CO2 in a cold-finger cooled with liquid N₂ (ref. 31). Total CO₂ production was measured from the IR absorbance of expired air sampled continuously from a metabolic tent, or collected over 5 min in 100-l Douglas bags Alkalisoluble muscle protein from fat-free, dried biopsy samples was hydrolysed and leucine was separated preparatively on a Locarte amino acid analyser Leucine-CO2 was liberated by ninhydrin at pH 2, dried and its enrichment measured in the isotope ratio mass spectrometer. Muscle protein synthesis, k_{μ} may be obtained by comparing the change in ¹³C enrichment of leucine incorporated into protein in two muscle biopsy samples taken some hours apart, but at times (t_1, t_2) when the blood leucine or α -KIC pools are enriched to plateau values. Synthesis rate, $k_a = \Delta E_{\rm muscle}/\Sigma_1^{r_1} E_{\rm blood} \Delta l \times 100 \; {\rm h}^{-1}$ where $\Delta E_{\rm muscle}$ is the change in enrichment of muscle and $\Sigma E_{\rm blood}$ is the integral of blood over the time in h. Note in the figure that with an assumed initial zero (that is, background) enrichment of muscle-protein leucine (as measured in muscle from surgical patients, in mixed blood proteins and in casein), incorporation of ¹³C into muscle protein is essentially linear with time. There is thus little error in calculating synthesis on the basis of either the change in enrichment between the biopsies compared with the plateau of blood leucine or α -KIC enrichment, or the incorporation of ¹³C-leucine into muscle obtained by a single biopsy at the end of the whole period of infusion, compared with the integrated weighted-mean blood leucine (or α -KIC).

Table 1 Skeletal muscle and whole-body protein synthesis in normal adults and boys with Duchenne muscular dystrophy

Whole-body protein turnover	Normal adults $(n = 7)$	Boys with DMD $(n=5)$
Body weight (kg)	80.8 ± 19.2	54±6.5*
Leucine flux Q	194 ± 20	140±39
(µmol per kg per h)	17.1-20	1.0207
Leucine intake I	55±4	64 ± 10
(μmol per kg per h)		**
Leucine oxidation O	40±8	$63 \pm 30*$
(µmol per kg per h)		
Protein synthesis S	154 ± 30	$77 \pm 22*$
(µmol leucine per kg per h)		
(g protein per 12 h)	212 ± 41	81 7 ± 23*
Muscle protein synthesis		
Synthesis rate (% h ⁻¹)	0.198 ± 0.055	0.066 ± 0.028 *
Muscle mass (kg)	31.1 ± 7.7	$6.4 \pm 3.0*$
Muscle protein synthesis (g per 12 h)	113 ± 31	17 5±7.42*
Urinary 3-methylhistidine/creatinine (molar ratio×10 ³)	19.0 ± 2.4	55.2±5.4*

Data are mean ±s.d. for volunteers, consisting of seven healthy adult males (aged 22-65 yr) and five children with Duchenne muscular dystrophy, aged 12-18 yr. Subjects were infused intravenously with carboxyl-labelled ¹³C-leucine (enriched to 90 atoms % excess) for 7-8 h of the study while being fed a liquid milk-based food at hourly intervals (~0.1 g, protein, 14 kJ per kg body wt) Leucine flux and oxidation were calculated using equations given in ref. 7, except that the enrichment of blood α -ketoisocaproate rather than leucine was used as this is more likely to represent the labelling of the metabolic pool from which leucine is removed by protein synthesis and oxidation. The component of the flux not directly measured, protein synthesis (S), was obtained by manipulation of the data for flux (Q) and oxidation rate (Q), according to a two-pool stochastic model whereby in the steady state $\dot{Q} = \dot{S} + \dot{O}$ (that is, the sum of processes removing leucine)⁶. (See refs 7, 30, 31 for details of mass spectrometric analysis) Muscle synthesis rate was measured by ¹³C incorporation into leucine of mixed muscle protein of quadriceps (see Fig. 1) assuming that the precursor pool for protein synthesis was labelled similarly to a-KIC in blood. Urinary 3-methylhistidine and creatinine were measured in most normal subjects over 24 h on various occasions but were also measured during infusion of labelled leucine. In the case of the patients with muscle disease, values for urmary 3-methylhistidine and creatinine are the mean of estimates obtained over a number of days. There were no significant differences in the mean values of such estimates compared with those obtained during the period of infusion. Muscle mass was estimated from creatinine excretion (8 84 mmol of creatinine = 20 kg of muscle)13

* Significant difference (P < 0.01; Student's one-tailed t-test) from levels in normal fed men

was only 34% of that observed in the normal adults (that is, $0.066\%\ h^{-1}$), which is less than that observed during fasting in normal adults (unpublished results). This means that muscle protein synthesis contributes only 17.5 g protein per 12 h, 8.6% of whole-body protein synthesis. This depression of muscle protein synthesis is all the more marked when it is considered that in normal adolescent children who are still growing, the rates of whole-body and muscle protein synthesis are likely to be much higher than in adults.

The finding of a depressed rate of muscle protein synthesis associated with DMD was unexpected, particularly in view of the high 3-methylhistidine/creatinine ratio observed in the present patients and reported previously in other patients with this disease¹⁻³. 3-Methylhistidine occurs in actin and some species of myosin heavy chain, and as it is not metabolized in man its excretion should be a quantitative estimate of the rate of actin and myosin heavy chain degradation¹⁵. Creatinine excretion may be taken as an index of skeletal muscle mass¹³ (even in cases of muscle disease¹⁶); thus the threefold elevated 3-methylhistidine/creatinine ratio observed in boys with DMD has been taken to indicate a proportionally elevated rate of mvofibrillar degradation¹⁻³. In addition, as these patients were not actually losing muscle protein at a significant rate (on the basis of our repeated computerized tomography and creatinne excretion measurements), the rate of protein synthesis should therefore be increased compared with normal values. Clearly this conclusion does not agree with the rates of muscle protein synthesis measured here, and have no reason to believe that our direct measurements of the rate of muscle protein synthesis are substantially wrong. For this to be the case, enrichment of the true precursor leucine pool would have to be very much lower than the α -KIC enrichment in the patients compared

with the normal adult subjects, which is unlikely. On the other hand, we have already reported findings that raise doubts about the validity of the assumption that 3-methylhistidine excretion rates are a true reflection of skeletal muscle degradation rates 17-19. We have shown that in the rat, substantial amounts of 3-methylhistidine may derive from the degradation of actin in non-muscle tissues. Although the amounts of actin in tissues other than skeletal muscle is small, it is a ubiquitous protein and if its turnover rate in non-muscle tissues is high this could result in a substantial non-muscle contribution to the urine.

In fact the proportion of non-muscle sources of excreted 3-methylhistidine is likely to be much higher in the dystrophic patients than in normal subjects. We find, on the basis of creatinine excretion, body weight and total body potassium measurements, that although skeletal muscle mass is markedly reduced in these patients (to only 12% of body weight), nonskeletal muscle mass (normally 15% of body weight) is only reduced to 74% of normal. If creatinine excretion is depressed in proportion to the reduced muscle mass, non-muscle sources of 3-methylhistidine would inflate the 3-methylhistidine/ creatinine ratio, as has been observed in muscle waiting due to amyopathic lateral sclerosis²⁰. Given the 3-methylhistidine content of skin (0.6 µmol per g protein) and gastrointestinal muscle (1.8 µmol per g protein)²¹ and assuming that these two tissues comprise a normal proportion (47 and 13% respectively)22,23 of non-skeletal muscle tissues in patients with muscular dystrophy, then these tissues need only turn over at three to four times the rate of skeletal muscle to account for the excreted 3-methylhistidine. Studies of patients undergoing elective surgery have provided evidence that in man, skin and gut muscle do indeed turn over at about two and five times, respectively, the rate of skeletal muscle²⁴.

An elevated rate of protein degradation in diseased muscle has also been observed in animal models of the disease However, there is no animal model which reproduces exactly the features of the human disease. Indeed, in most of the animal models there is a transient muscle hypertrophy early on in the disease, and protein turnover measurements are most often made in animals at this stage. As we have pointed out elsewhere²⁵, increased protein turnover in muscle is often a feature of rapid growth and regeneration, which may account for the elevated turnover in these animal models26. There is no evidence to suggest that this occurs in adolescent boys with muscular dystrophy such as those studied here, although it may occur in very much younger patients with the disease.

A reduced rate of protein synthesis rather than an increased rate of protein degradation as the primary cause of growth failure in DMD has important implications for present disease therapies. The notion that increased degradation was the main factor led to suggestions (and testing in animal models) that proteinase inhibitors might prove effective. 27-29. However, suppression of muscle protein degradation falsely assumed to be elevated in patients would be of little value since protein synthesis is markedly depressed. The use of possible therapeutic agents to increase muscle protein synthesis would be much more rational. The present results demonstrate that it would be possible to monitor such effects over the short term.

The mechanism of the positive inotropic effect of digitalis glycosides remains unclear. One theory suggests a causal relationship between the binding to and consequent inhibition of (Na⁺+K⁺) ATPase (the sodium pump) by digitalis and an increased myocardial contractile force¹⁻⁶. By this mechanism, the increased force of contraction would occur secondary to an elevation of intracellular sodium concentration which then causes an increased intracellular concentration of calcium via a sodium-calcium exchange mechanism4-6. Another theory proposes that the binding of digitalis to (Na⁺ + K⁺)ATPase causes an increase in a sarcolemmal calcium pool⁶⁻⁹, suggesting that the inotropic effect could be due to a causal relationship between the formation of the digitalis-(Na++K+)ATPase receptor complex and increased myocardial calcium availability and utilization, exclusive of an inhibition of the sodium pump⁷ We now report that two distinct positive inotropic sites for ouabain exist in rat ventricular strips. The higher-affinity response (ED₅₀ = 0.5μ M) correlates with an apparent high-affinity site which can be detected by ³H-ouabain binding to intact rat ventricular myocytes. These higher-affinity sites do not correlate with concentrations (IC₅₀) of ouabain necessary to inhibit (Na++K+)ATPase activity of sarcolemma preparations prepared from rat ventricles, suggesting that in the rat ventricle the high-affinity site for the inotropic effect of ouabain may not be related to inhibition of (Na++K+)ATPase. The low-affinity site is, however, related to inhibition of this enzyme.

Figure 1 shows a typical cumulative dose-response curve of ouabain on isometric contractile force in rat right ventricular strips. In a series of identical experiments, a 'low concentration

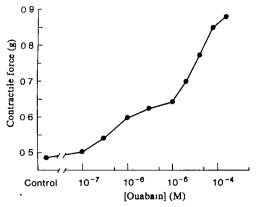

Fig. 1 Typical biphasic effect of ouabain (in mol l⁻¹) on isometric contractile force (in g) in rat ventricular myocardial strips. Right ventricular strips were prepared from adult rats as previously described¹¹ and vertically mounted in a water-jacketed muscle bath containing (in mM) 137 NaCl, 5.4 KCl, 1.8 CaCl₂, 1.05 MgSO₄, 0.4 KH₂PO₄, 12 NaHCO₃ and 10 glucose. This Tyrode solution was aerated with 95% O₂-5% CO₂ and maintained at a pH of 7.0 at 35 °C. The strips were allowed to equilibrate for 60 min while electrically paced at 1 Hz (via punctate platinum electrodes) with a stimulus duration of 2 ms and voltage at 20% above threshold (6–8 V) During this equilibration period, the preload was constantly adjusted to 1 g. A single cumulative concentration-response curve for ouabain was obtained for each ventricular strip. For the experiment shown, the apparent ED₂₅s were estimated to be 0.5 and 19 μM.

effect' occurred between 0.1 and 10 µM ouabain, with an increase in contractile force of $34 \pm 5\%$ (n = 25) above control, while a 'high concentration effect', with a maximal increase of $84 \pm 9\%$ (n = 25) above control contractile force, occurred with 80-160 µM ouabain. Although the increase in contractility was undoubtedly produced by a complex series of events, the obvious biphasic nature of the ouabain dose-response curve (Fig. 1) is consistent with the existence of two separate glycoside receptor sites. We have therefore estimated two ED50 values from the experimental data. The high-affinity site had an ED₅₀ of $0.53\pm0.08 \,\mu\text{M}$ (assuming that the inflection point in the curve at 10⁻⁵ M represents the maximum effect of this site) and the low-affinity site had an ED₅₀ of $19\pm2\,\mu\text{M}$. Neither β adrenoreceptor blockade (20 µM sotalol) nor pretreatment of the rats with reserpine had any effect on the biphasic nature of the curve, the maximal increases in contractile force or the apparent ED₅₀ values for the low or high concentration effects, but the low-dose effect could be removed by prolonged washing. Erdmann et al.10 recently reported that rat ventricular strips had a single ouabain inotropic receptor with an ED₅₀ of 0.3 μM. This value is lower than found by us¹¹ and may be due to the fact that Erdmann et al. 10 were unable fully to elicit the high concentration effect, because in their preparations toxicity occurred at ouabain concentrations >30 µM.

In the same experimental conditions used to study rat ventricular strips, we obtained only a monophasic concentration-response curve for rat left atria (ED₅₀ = $45 \pm 9 \,\mu$ M), which is consistent with earlier reports of the positive inotropic effects of digitalis glycosides in rat myocardium¹¹. Similarly, only monophasic response curves were obtained for cat, rabbit and guinea pig ventricular papillary muscles or left atria. Thus, two inotropic receptor sites for ouabain seem to exist in rat ventricle that are perhaps less easily detectable in rat atria or myocardium of the other species.

Although most studies of ${}^{3}H$ -ouabain binding to various membrane preparations and purified $(Na^{+}+K^{+})ATP$ ases reveal a single class of ouabain binding site 12 , several workers have recently obtained results consistent with the existence of two populations of such sites ${}^{11,13-17}$. In an effort to detect two receptor sites of different affinities, we elected to examine ${}^{3}H$ -ouabain binding to isolated myocytes 18,19 instead of to membrane preparations, for two main reasons. First, it is likely that cell membrane preparations from ventricular myocardium contain $(Na^{+}+K^{+})ATP$ ase(s) from more than one cell type, including fibroblasts and postganglionic sympathetic nerves, which probably have different affinities for ouabain, particularly in

the rat¹⁷. Second, the preparative procedure for cardiac sarcolemma can potentially alter the configuration of all membranes and thus artificially create more than one apparent population of receptors.

The method of Akera and Cheng²⁰ was used to examine 3 H-ouabain binding to isolated rat ventricular myocytes. A $K_{
m D}$ value can be calculated from data obtained in a displacement assay (Fig. 2) by subtracting the concentration of the labelled ouabain (a) from the concentration of unlabelled ouabain ($C_{0.5}$) which causes a 50% displacement of the labelled ligand. Using concentrations of labelled ouabain of $0.1 \,\mu\text{M}$ (n=3) and $0.2 \,\mu\text{M}$ (n = 3), we obtained from probit plots $C_{0.5}$ values of $0.225 \pm 0.066 \,\mu\text{M}$ and $0.322 \pm 0.028 \,\mu\text{M}$, respectively, to give an average $K_D \pm s.d.$ of $0.124 \pm 0.090 \mu M$. Akera and Cheng²⁰ emphasize that this calculation of K_D applies only to a single class of site and that the binding reaction must be at equilibrium. Although equilibrium is difficult to obtain in ouabain-sensitive species, which have slow dissociation rates^{5,21,22}, equilibrium binding of ³H-ouabain to rat cardiac (Na⁺+K⁺)ATPase can be achieved rapidly due to a high dissociation rate^{5,21}. We found 30 min sufficient for equilibrium binding in our studies (data not shown). Because of large variability in the data obtained at the higher concentrations of unlabelled ouabain (where labelled ligand binding is low) we could not determine whether or not there was a second, lower-affinity site for ouabain binding. Such a low-affinity site clearly exists, as the IC₅₀ for inhibition of our rat cardiac sarcolemma preparation is 50 µM, similar to previously reported values for rat heart (Na⁺+K⁺)-ATPase^{11,21-25}. This low-affinity site for enzyme inhibition agrees well with that for positive inotropy (Fig. 1). Thus, our results are not consistent with the conclusion of Erdmann et al.10 that there is a complete dissociation of the positive inotropic effect of ouabain from the low-affinity site.

Studies reported by Godfraind and Ghysel-Burton²⁶⁻²⁸ on ouabain uptake, tissue electrolyte content and contractile force in guinea pig atria, and experiments reviewed by Noble²⁹ on

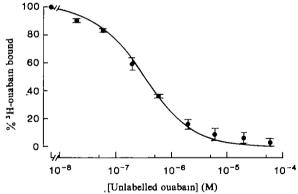

Fig. 2 ³H-ouabain binding to intact ventricular myocytes, isolated from adult rat myocardium as previously described^{18,19} The curve shows the effect of increasing amounts of unlabelled ouabain on the binding of 0.2 μM ³H-ouabain (100% binding) to myocytes in the presence of Krebs-Ringer bicarbonate buffer containing (in mM) 118.5 NaCl, 2.6 KCl, 0.5 CaCl₂, 1.18 MgSO₄, 1.18 KH₂PO₄, 14.5 NaHCO₃, 11.1 glucose and 2.0% (w/v) bovine serum albumin (Miles fraction V); the final incubation volume was 2 ml To each assay tube (5 ml Teflon beakers) 200 μl of ³H-ouabain (1 μM, 17 Ci mmol⁻¹ in aqueous solution) were added with appropriate amounts of unlabelled ouabain (stock solutions prepared in Krebs-Ringer bicarbonate buffer). After preincubation for 15 min in a shaking water bath (37 °C) aerated with 95% O2 and 5% CO2 in a closed hood, the binding reaction was initiated by the addition of 0.5 ml of cells ($\sim 4 \times 10^4$ cells). The reaction was terminated after 30 min by transferring the incubation beakers to an ice bath, followed by rapid filtration on Whatman GF/C glass fibre filters. The beakers were rinsed with 10 ml cold KCl (100 mM) and this rinse was used to wash the filters (filtration and wash time was ~5 s) The filters were placed in vials and incubated for at least 10 h in scintillation fluid before determination of radioactivity. External standards were prepared using ³H-ouabain and nonspecific binding was defined as the bound radioactivity not displaced by 5.5×10^{-3} M outbain, which was $\sim 30\%$ of the total binding in the absence of any added unlabelled ouabain. The curve shown is predicted from the equation, $\%^3$ H-ouabain bound = $100/(1+C/C_{0.5})$ where C = concentration of unlabelled outbain and $C_{0.5} = K_{\rm D} + a$, with $a = 0.2 \,\mu{\rm M}$ and $K_{\rm D} = 0.125 \,\mu{\rm M}$. Each point represents the mean (±s.e.m.) of three separate assays with a concentration of 0 2 µM 3H-ouabain.

potassium-sensitive reversal potentials, current-voltage relations and twitch tension in sheep Purkinje fibres, have suggested the presence of two ouabain binding sites of high and low affinity, related to Na+,K+-pump stimulation and inhibition, respectively. Low doses of ouabain (~10⁻⁸ M) can often produce a small but reversible negative inotropic effect, which may be transient^{29,30}. Our results, obviously consistent with the presence of two ouabain binding sites, show a reproducible positive inotropic effect of ouabain at levels corresponding to binding of the glycoside to a high-affinity site. This positive inotropy cannot be causally dependent on an overall decrease in sodium gradient if the direct or indirect effects of low doses of ouabain are to produce a net stimulation of the Na+,K+pump²⁹

The striking discrepancy between the apparent IC₅₀ value for ouabain inhibition of rat heart (Na⁺+K⁺)ATPase and the $K_{\rm D}$ of the higher-affinity ouabain binding site reported here, suggests that there may be no relationship between Na+,K+pump inhibition and the low concentration inotropic effect in rat ventricle. However, the high-affinity ouabain binding site may represent only a small fraction of the total number of $(Na^+ + K^+)$ ATPase molecules in rat ventricle, the majority being of the lower-affinity type. In this case, inhibition at the higheraffinity site by low concentrations of ouabain may produce a limited increase in internal sodium (and secondarily of calcium), because the pump still has sufficient 'gain' to keep internal sodium relatively low. At higher glycoside concentrations, binding to the low-affinity site reduces pump gain and internal sodium will rise rapidly. The exact shape of the force-binding curve will depend on the relationship between internal sodium and force, which is not simple³¹, but a biphasic response would not be surprising. This hypothesis is difficult to test experimentally, as we cannot detect a change in rat cardiac (Na++K+)ATPase activity at ouabain concentrations below 1 μM. Alternatively, the higher-affinity site may exist as a catalytically inactive conformation or isozyme of (Na++K+)-ATPase. In this case, high-affinity binding of ouabain in vivo would not result in pump inhibition, but perhaps induce a conformational change in the enzyme (and enzyme-associated membrane lipids) which could increase calcium binding to sarcolemma^{7,9,15}.

Thus, ouabain binding to the higher-affinity $(Na^+ + K^+)$ -ATPase in rat ventricular sarcolemma could result in increased calcium mobilization and availability to the myofibrils, producing the low-concentration positive inotropic effect in isolated rat ventricular muscle. These effects could occur independently of Na⁺,K⁺-pump inhibition. With increasing concentrations of ouabain, binding to the lower-affinity site would occur, resulting in Na⁺,K⁺-pump inhibition, enhanced Na⁺-Ca²⁺ exchange and a more pronounced positive inotropic effect. While there appears to be a clear distinction between the two sites as well as between the two inotropic phases in rat ventricular myocardium, these differences in myocardium of ouabain-sensitive species may be small and thus difficult to detect if, in fact, two populations of ouabain sites actually exist.

Nanomolar concentrations of extracellular ATP activate membrane Ca channels in snail neurones

A. Yatani, Y. Tsuda, N. Akaike & A. M. Brown*

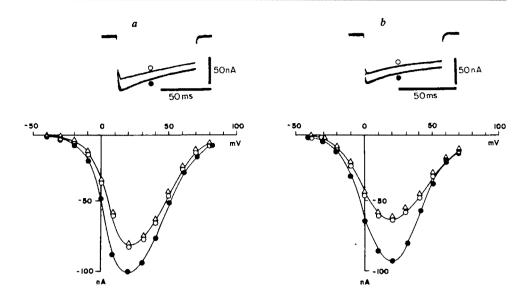

Department of Physiology and Biophysics, University of Texas Medical Branch, Galveston, Texas 77550, USA

Intracellular ATP is known to affect the electrical properties of membranes indirectly by acting intracellularly as a substrate for ATPases such as (Na++K+)ATPase, Ca2+-ATPase or adenylate cyclase. More recently, extracellular ATP has been shown to act on effector cells innervated by autonomic nerves and a purinergic receptor hypothesis has been proposed for this effect^{1,2}. Extracellular ATP also acts on the slow inward current. In of cardiac muscle membranes 3,4 where the effect may be coupled to a change in intracellular metabolism. These observations raise the possibility that extracellular ATP (ATP.) might alter the Ca current of excitable membranes. The Ca current is of major interest because it acts as the trigger for many cellular functions such as secretion, contraction, motility and luminescence. To test our idea, we examined the effects of ATP. on a well studied Ca current, that of neuronal membranes. As we report here, ATP, in nanomolar to micromolar concentrations produced substantial increases of I_{Ca} , and the non-hydrolysable congener of ATP, adenylylimidodiphosphate (AMP-PNP) had an even greater effect. By contrast, intracellular perfusion of ATP in nanomolar quantities had no effects on I_{Ca} , but with 10⁻⁵-10⁻³ MATP small increases were observed. Intracellular perfusion with AMP-PNP at these doses had no effect on I_{Ca} . We conclude that ATP, enhances membrane Ca channel activity by an as yet undetermined mechanism.

The experiments were performed on identifiable neurones from the suboesophageal ganglia of Helix aspersa, usually F1, F2 and E1, E2 according to Kerkut et al.5. The nerve cell bodies were isolated by dissection and aspirated into a suction pipette for internal perfusion and voltage clamp⁶⁻⁸. A separate intracellular micropipette provided the membrane potential signal for the clamp circuit. K currents were suppressed by tetraethylammonium (TEA) 50 mM extracellularly, 4-aminopyrine (4-AP) 5 mM extracellularly, TEA 10 mM intracellularly, and substitution of K ions by Cs ions intra- and extracellularly. Na currents were suppressed by Tris substitution for Na ions extracellularly and Na ions were absent from the intracellular solution. Intracellular Ca activity was buffered to 10⁻⁸ M by 0.1-1.0 mM EGTA. In these conditions two currents are present over the potential range of -50 to +50 mV-a linear, non-voltage-dependent, non-time-dependent leakage current and I_{Ca} (ref. 8). Leakage and linear components of capacitative currents were eliminated by adding to a pair of voltage-clamp

^{*}To whom correspondence should be addressed

Fig. 1 Effects of extracellular ATP (a) and AMP-PNP (b) on I_{Ca} (current was corrected for linear components of leakage capacitance by the subtraction method described in text). The compositions of perfusion solutions (in mM) were: internal: Csaspartate, 135; TEA-OH, 10; Tris-base, (pH 7.3); external: Tris-Cl, 35; CsCl, 5; TEA-Cl, 50; CaCl2, 10; MgCl2, 15; 4-AP, 5; glucose, 5.5, Tris-base, HEPES, 20 (pH 7.4). All chemicals were added to the control solutions immediately before use. a, Upper panel shows the effect of ATP (10^{-6} M) on I_{Ca} elicited by a 70 ms pulse to +20 mV from a holding potential of -50 mV before (O) and 15-20 min after (●) the addition of ATP. Bottom panel shows voltage-current relationships of peak Ca current control (O), 15-20 min after ATP (10⁻⁶ M) (•)

and 60 min after washout (\triangle). b, Upper panel shows the effect of AMP-PNP (10^{-8} M) on I_{Ca} with the same pulse protocol as in a before (\bigcirc) and 15 min after (\bigcirc) the addition of AMP-PNP. Bottom panel shows voltage-current relationships of peak Ca current control (\bigcirc), 15-20 min after AMP-PNP (10^{-8} M) (\bigcirc) and 60 min after washout (\triangle).

steps from the holding potential, $V_{\rm H}$, of $-50\,{\rm mV}$ the current responses that were equal in amplitude but opposite in sign. At potentials more positive than $+50\,{\rm mV}$, a time-dependent, nonspecific outward current also appears but these potentials were rarely used in the present experiments and when they were used, nonspecific leakage current was corrected for by subtracting the current that remained after blockage of $I_{\rm Ca}$ by Co substitution for Ca.

The effects of extracellular ATP and AMP-PNP were observed after control currents had been steady for 30-60 min (see Fig. 1). ATP in concentrations of 5×10^{-9} to 10^{-8} M produced an immediate increase in I_{Ca} which continued until a new steady-state level was attained within 5-10 min. Maximum effects were observed at about 10^{-4} M ATP and were similar for Tris, Na and Li salts of ATP, the effects being reversible. AMP-PNP produced the same effect as ATP (Fig. 1b). The increases in I_{Ca} amplitude occurred without any apparent changes in the kinetics of activation, and although inactivation occurred at a slightly faster rate for the largest currents, this may be related to Ca-current-dependent inactivation^{8,9}. There were no changes in leakage currents. The increase in Ca currents was not voltage dependent (Fig. 1a, lower panel), as the curves of peak current versus voltage before and after ATP were simply scaled versions of each other. This rules out a surface charge effect due to ATP adsorption which would also be unlikely at such low concentrations. As the peak Ca currents are little affected by inactivation, which is at least 10 times slower than activation, and as there is no steady-state inactivation of I_{Ca} at the holding potential of -50 mV used in these experiments, the ATP_o effects must be due mainly to an increase in the channel steady-state activation process. This could result from an increase either in the number of conducting units or in the average unit conductance of channels already present.

Figure 2 shows the dose–response relationship for ATP_o and AMP-PNP_o actions on peak I_{Ca} . The respective average maximal increases were $125\pm16\%$ and $130\pm16\%$ (mean \pm s.d.) with n=6 for ATP_o and n=7 for AMP-PNP_o. The K_0 , is 10^{-6} M for ATP and 3×10^{-9} M for AMP-PNP. At higher concentrations $(10^{-3}$ M) the response falls from its maximum value but we have not further investigated the response at these unphysiological concentrations.

One possible explanation of how ATP_o activates Ca channels is that ATP acts as a substrate for an outward-facing membrane ATPase. However, this would require hydrolysis of the molecule, which is ruled out by the effects of the non-hydrolysable congener, AMP-PNP. Another possibility is an outward-facing

adenylate cyclase, but extracellular cyclic AMP had no effect on I_{Ca} . Alternatively, ATP may permeate these particular neuronal membranes and act as a substrate for adenylate cyclase located in the membrane interior. Investigation of this possibility by perfusing ATP and AMP-PNP intracellularly revealed that ATP produced small increases of I_{Ca} , but required concentrations of ≥10⁻⁵ M to achieve the effect, and that AMP-PNP was ineffective even at 10⁻² M. The effects appeared within 10 min and were steady by 15 min. Hence, the present results are not due to ATP_o acting as a substrate for a membrane system that activates Ca channels. They may be due to a specific reaction between ATP_o and the membrane, as suggested by the purinergic hypothesis, or a mechanism similar to that proposed for the β -adrenergic receptor reaction $^{10-12}$ might exist. In this case the ATP-receptor complex would activate adenylate cyclase to increase cyclic AMP and thus I_{Ca} . Extracellular cyclic AMP had no effect on I_{Ca} but intracellular perfusion at concentrations of 10⁻⁵ M produced a small increase. This hypothesis would require that the complex amplify adenylate cyclase activity because ATP applied intracellularly in micromolar quantities had much smaller effects than ATP or AMP-PNP applied extracellularly in nanomolar amounts. Extracellular application of ATP might then be enhanced by prior intracellular perfusion with ATP. We tested this proposal using millimolar concentrations of ATP, and found that further increases of I_{Ca} occurred in response to ATPo. However, the effects seemed to be simply additive and the results were inconclusive. We therefore tried

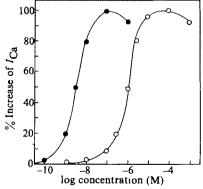

Fig. 2 Dose-response curves for the effects of extracellular ATP (\bigcirc) and AMP-PNP (\blacksquare) on I_{Ca} (elicited by a 70 ms long pulse to +20 mV from holding potential of -50 mV). Each point represents the mean of six measurements for ATP and seven for AMP-PNP obtained from different neurones (curves were drawn by eye).

the opposite experiment, to deplete the cell of ATP, and observe the effect of ATPo. To do this we perfused internally with oligomycin, 10⁻⁶ M (Sigma), or ruthenium red, 5×10⁻⁴ M (Sigma). Although the response to extracellular ATP was reduced in these experiments, the Ca currents in the presence of the metabolic inhibitors were also declining, thus preventing any firm conclusion regarding cyclic AMP as a second messenger.

We studied the potency of phosphorylated adenosine and guanosine compounds and found the sequence to be AMP-PNP » ATP > ADP, with AMP and adenosine having no effect. We also found that GTP (Sigma) was about as effective as ADP and that GMP-PNP was as effective as AMP-PNP. Furthermore, the putative purinergic antagonists, apamin (Sigma) 5× 10⁻¹⁰ M, quinidine (Sigma) 10⁻⁶ M, propranolol (Sigma) 10⁻⁶ and phentolamine (Sigma) 10⁻⁷ M, had no effect on the response to ATPo. Thus, from the above results the mechanism whereby ATPo activates Ca channels remains uncertain.

Human melanoma-associated antigen p97 is structurally and functionally related to transferrin

Joseph P. Brown*, Rodney M. Hewick†, Ingegerd Hellström*, Karl Erik Hellström*, Russell F. Doolittle & William J. Drevert

*Program in Tumor Immunology, Fred Hutchinson Cancer Research Center, Seattle, Washington 98104, USA †Division of Biology 156-29, California Institute of Technology, Pasadena, California 91124, USA Department of Chemistry D-006, University of California, San Diego, La Jolla, California 92093, USA

p97 is a 97,000-molecular weight (MW) cell-surface glycoprotein, which is present in most human melanomas but in only trace amounts in normal tissues1-4. We describe here the purification of p97 by affinity chromatography with monoclonal antibody, followed by SDS-polyacrylamide gel electrophoresis (SDS-PAGE), and determination of the N-terminal amino acid sequence using a new, highly sensitive protein sequencer⁵. The sequence was found to be homologous to the N-terminal sequences of transferrin and lactotransferrin. This structural homology was confirmed by the observation that antiserum to denatured p97 cross-reacted with denatured transferrin and lactotransferrin. We have also demonstrated that p97 is functionally related to transferrin and lactotransferrin in that it binds iron. This is one of the first reports of the amino acid sequence of a human tumour-associated cell-surface antigen and one of the few cases in which insight has been obtained into

p97 was purified by affinity chromatography. Monoclonal IgG2a antibody specific for p97 was added to a detergent lysate of melanoma cells, and the mixture was passed through a protein A-Sepharose CL-4B column. The antibody and p97 were eluted from the adsorbent at pH 5. The proteins were reduced with 10 mM dithiothreitol (DTT) and alkylated with 50 mM iodoacetamide, and p97 was separated from the IgG heavy and

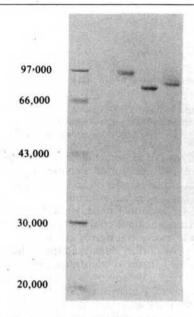

Fig. 1 Purification of p97. SK-MEL 28 melanoma cells (10 g) were suspended in 40 ml 20 mM Tris-HCl buffer pH 8.0, containing 100 mM NaCl, 1 mM EDTA and 0.5% Nonidet-P40 (TNEN buffer) supplemented with 1 mM phenylmethylsulphonyl fluoride (PMSF), and the lysate was centrifuged at 300,000g at 4 °C for 1 h. Antibody $96.5 (5 \mu g ml^{-1})^4$ was added, and the lysate was passed through a 1 ml column of protein A-Sepharose CL-4B at 4 °C. The column was washed, then eluted with 2 ml of 100 mM citrate buffer pH 5, containing 0.5% Nonidet-P40. The proteins were precipitated with 60% methanol containing 0.6% acetic acid at -20°C and electrophoresed on a SDS-6% polyacrylamide gel as described elsewhere 14, except that 5 mM sodium mercaptoacetate was added to the sample buffer. The gel was stained with Coomassie blue, and p97 was eluted by overnight incubation at 20 °C in 0.2 M Tris-acetate buffer pH 8.0, containing 0.1% DTT and 1% SDS, followed by electrophoretic elution in 50 mM Tris-acetate buffer pH 7.8, containing 0.5 mM sodium mercaptoacetate and 0.1% SDS, and then in 50 mM ammonium bicarbonate containing 0.1% SDS. The figure shows a stained SDS-10% polyacrylamide gel of: a, molecular weight markers phosphorylase b (97,000), serum albumin (66,000), ovalbumin (43,000), carbonic anhydrase (30,000) and soybean trypsin inhibitor (20,000); b, purified p97; c, transferrin; d, lactotransferrin.

light chains by preparative SDS-PAGE. Approximately 50 µg of p97 were obtained from 10 g of cells. The purified protein electrophoresed as a single, narrow band on an analytical SDSpolyacrylamide gel (Fig. 1). It appeared to be slightly smaller than phosphorylase b (MW 97,000) and significantly larger than human transferrin and lactotransferrin (MW ~80,000). The immunological specificity of the purification procedure was established using control IgG2a antibodies. As p97 comprised < 0.1% of the protein in the initial cell lysate, the two-step procedure resulted in a > 1,000-fold purification.

Amino acid sequence analysis⁵ of purified p97 yielded a sequence of 12 residues at the N-terminus (see Fig. 2). A computer search of the Newat amino acid sequence library6 revealed that this sequence is homologous to the N-terminal sequence of transferrin7, seven of the 12 residues being identical (Fig. 2). We consider that this homology is significant for two reasons: first, the two least common amino acid residues, Trp and Cys, are among those conserved, and second, six of the seven conserved residues are also conserved at the N-terminus of lactotransferrin8 (Fig. 2). On the basis of the limited amount of sequence data available, p97 appears to be as closely related to transferrin and lactotransferrin (~50% identity) as these proteins are to one another. For comparison, haemoglobin α and β chains have 44% identity⁶. We conclude that p97, transferrin and lactotransferrin have evolved from a common

Independent evidence for the structural relationship between p97 and transferrin and lactotransferrin was obtained by

p 9 7	Gly Met Glu	Val Arg Trp Cys Ala Thr Ser Asp ? G	ilu
Transferrin Val Pro	Asp Lys Thr	Val Arg Trp Cys Ala Val Ser Glu His G	lu l
Lactotransferrin Gly Arg Arg	Arg Arg Ser	Val Gin Trp'Cys Ala Val Ser Gin Pro G	alu

Fig. 2 N-terminal amino acid sequences of p97, transferrin and lactotransferrin. The N-termini are shown at the left. In the p97 sequence, the Gly and Ser residues are tentative, the Cys residue was detected as S-amidomethylcysteine phenylthiohydantoin, and the twelfth residue was not detected. Conserved amino acid residues are boxed.

serological analysis. An antiserum obtained by immunizing mice with denatured p97 recognized denatured p97 and cross-reacted with denatured transferrin and lactotransferrin (Fig. 3). As a negative control, serum albumin was not recognized by the antiserum. On the other hand, we did not observe cross-reactions when mouse monoclonal antibodies to native p97 and rabbit antisera to native transferrin and lactotransferrin were tested. We conclude that denatured p97 shares antigenic determinants with denatured transferrin and lactotransferrin, and that these antigenic determinants presumably are conserved amino acid sequences. Antiserum to denatured p97 may prove useful in searching for additional members of the transferrin family.

Transferrin and lactotransferrin bind iron with high affinity. To determine whether p97 also binds iron, we incubated melanoma cells with ⁵⁹Fe, lysed them with non-ionic detergent, added monoclonal antibody to the lysate and passed the mixture through a protein A-Sepharose column. When antibodies specific for p97 were used, the column retained ~4% of the ⁵⁹Fe, showing that a significant proportion of the iron taken up by the cells was bound to p97. In control experiments using no antibody and four antibodies not specific for p97, including two antibodies specific for other melanoma cell-surface proteins, <0.05% of the ⁵⁹Fe was retained (Fig. 4). We conclude that p97 at the surface of viable melanoma cells can bind iron.

On the basis of the similar molecular weights of p97 and the transferrin receptor on SDS-PAGE after reduction, it has been suggested that two proteins are identical⁹; however, our results do not support this. First, the tissue distribution of p97 differs

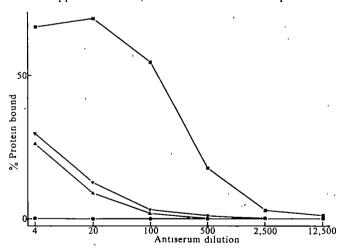

Fig. 3 Serological cross-reaction of p97 with transferrin and lactotransferrin. An antiserum to denatured p97 was obtained by immunizing BALB/c mice with p97 that had been reduced, alkylated and purified by SDS-PAGE. The mice were given ~5 μg antigen emulsified in 0.5 ml complete Freund's adjuvant intraperitoneally, were boosted 4 and 6 weeks later with antigen in incomplete adjuvant, and were bled 2 weeks after the last immunization. Proteins radioiodinated as described previously to a specific radioactivity of 10⁸ c.p.m. μg⁻¹, and purified by SDS-PAGE without previous alkylation (4,000 c.p m in 15 μl TNEN buffer) were incubated with 5 μl antiserum at 0 °C for 2 h. Formalin-fixed Staphylococcus aureus (10 mg) were added in a volume of 1 ml and after 5 min at 0 °C were pelleted and washed with 1 ml TNEN buffer. Normal mouse serum tested as a negative control bound <0.5% of each protein. ■, p97, ▲, transferrin; ●, serum albumin.

from that of the transferrin receptor^{2,9-11}. Second, on SDS-PAGE without previous reduction, p97 migrates slightly faster than the reduced protein⁴; in these conditions the transferrin receptor migrates as a dimer with a MW of ~200,000 (refs 9, 12). Third, monoclonal antibody OKT9, which is specific for the transferrin receptor⁹, did not immunoprecipitate p97 from radioiodinated melanoma cells, and antibodies specific for p97 did not immunoprecipitate the transferrin receptor from radioiodinated melanoma or leukaemia cells. Sequential immunoprecipitation experiments confirmed that the molecules immunoprecipitated by these antibodies were distinct. Finally, p97 did not bind to a transferrin-Sepharose column (data not shown). Clearly, p97 and the transferrin receptor described⁹⁻¹¹

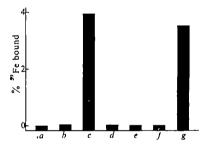

Fig. 4 Binding of 59 Fe by p97 Confluent SK-MEL 28 cells were washed three times with 25 ml phosphate-buffered saline (PBS) pH 7.2, and incubated at 37 °C for 1 h with 10 ml PBS containing 2 mM NaHCO₃, 1 mM sodium citrate and 10^7 c.p.m. 59 FeCl₃. A cell lysate, prepared as described in Fig. 1 legend, contained 4×10^4 c.p.m. 59 Fe. Monoclonal IgG2a antibody ($20 \, \mu g \, \text{ml}^{-1}$) was added to the lysate, and the mixture was passed through a 0.2 ml protein A-Sepharose CL-4B column, which was washed with 2 ml TNEN buffer. Results are expressed as % ⁵⁹Fe retained by each column: a, no antibody; b, antibody 103.1, specific for a cell-surface glycoprotein common to most human cells; c, antibody 96.5, specific for p97; d, antibody 10.9, specific for a mouse immunoglobulin allotype; e, antibody W6/32, specific for HLA-A, B, C; g, antibody 118.1, specific for p97.

are not identical, although amino acid sequence studies of the receptor should elucidate whether these molecules have any structural homology.

Our data show that p97 is structurally related to transferrin and lactotransferrin, and like these p97 binds iron. However, unlike transferrin and lactotransferrin, which are present in serum and milk (and other secretions) respectively, p97 is synthesized by melanoma cells and appears to be an integral membrane protein⁴. The presence of p97 at the surface of certain cell types suggests that its function may be translocation of iron.

Although p97 and the transferrin receptor are structurally distinct, their proposed functions are similar. Recent evidence confirms that the transferrin receptor recognized by monoclonal antibodies⁹⁻¹¹ does indeed mediate cellular uptake of transferrin-bound iron, as a monoclonal antibody specific for the receptor blocks uptake of transferrin and iron by leukaemia cells¹³. Our proposed function for p97 in iron translocation, however, has not been evaluated by functional studies. Given that normal adult tissues contain only trace amounts of p97, their iron uptake is more likely to be mediated by the transferrin receptor than by p97. The restricted tissue distribution of p97 (large amounts are present only in melanomas, nevi and fetal intestine)

implies a more specialized role for this protein, possibly related to particular aspects of iron metabolism in these tissues.

Ribosomal RNA transcription in vitro is species specific

Ingrid Grummt*, Erika Roth* & Marvin R. Paule†

*Institut für Biochemie der Universität Würzburg, Röntgenring 11, D-8700 Würzburg, FRG

†Department of Biochemistry, Colorado State University, Fort Collins, Colorado 80523, USA

Eukaryotic cells possess three distinct nuclear DNA-dependent RNA polymerases which are responsible for transcription of different sets of genes (for review see refs 1, 2). Recently, cell-free transcription systems have been developed which faithfully initiate transcription of isolated genes by the corresponding RNA polymerase in the presence of crude cellular extracts. These cellular extracts supply additional components required for specific transcription³⁻⁵. Successful *in vitro* systems for transcription of RNA polymerase II or III genes were developed using either heterologous or homologous components⁷⁻¹¹. In contrast, an analogous cell-free system for the RNA polymerase I transcription unit from mouse has been shown to be active only with homologous extracts from mouse cells⁶. Data presented here show that in vitro transcription of ribosomal DNA isolated from mouse, human and a protozoan requires completely homologous components. None of the three active cell-free systems is capable of correct initiation on the nonhomologous templates. Further, supplementation of mouse extracts with purified protozoan RNA polymerase I failed to result in specific transcription of the protozoan rDNA, suggesting that the species specificity of pre-ribosomal RNA synthesis resides, in part, in the transcription factors.

It had been shown previously that specific transcription of rDNA from mouse requires transcription factors from mouse cells; neither human KB cell extracts nor frog oocyte or egg extracts could substitute for extracts from mouse cells⁶. One suggested explanation of this result was that species-specific factors might be involved in the expression of RNA polymerase I genes. We have investigated this apparent species specificity by assaying several different cloned ribosomal RNA genes for their ability to be selectively and correctly transcribed in the mouse extract system. Cloned ribosomal DNAs from Physarum polycephalum, Drosophila melanogaster and Xenopus laevis were used alone or in combination with mouse rDNA as templates in the cell-free transcription system derived from cultured Ehrlich ascites cells. The site of transcription initiation for each of these rDNA genes is known and thus the length of specific in vitro

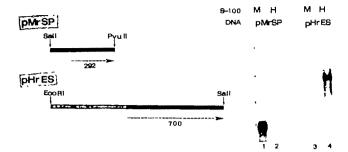

Fig. 1 In vitro transcription of rDNAs from mouse and man by homologous and heterologous cell-free transcription systems. One microgramme of cloned mouse rDNA truncated with PvuII (pMrSP/PvuII, lanes 1, 2) or human rDNA truncated with SalI (pHrES/SalI, lanes 3, 4) was incubated for 1 h at 30 °C in a 50-µl reaction mixture containing 10 mM HEPES (pH 7.9), 75 mM KCl, 5 mM MgCl₂, 0 05 mM EDTA, 0.5 mM dithiothreitol, 10% glycerol, 10 mM creatine phosphate, 600 μ M each of ATP, CTP and UTP, 50 μ M GTP, 3 μ Cı of [α - 32 P]GTP (specific activity 10–25 Cı mmol $^{-1}$) and 25 µl of S-100 extract S-100 extracts were prepared as described by Weil ecal from cultured Ehrlich ascites tumour cells (EA) or from HeLs cells (HeLa) Synthesis was terminated by addition of 50 µl or 100 mM sodium acetate, 0 5% SDS and 25 µg Eschenchia coli tRNA RNAs were extracted with phenol and chloroform, precipitated with ethanol and separated by electrophoresis on a 4% polyacrylamide gel as described by Weil et al.⁴. Autoradiograms of the gel are shown Lane 1 pMrSP/PvuII DNA+ Ehrlich ascites S-100 extract. Lane 2: pMrSP/PvuII DNA+HeLa S-100 extract Lane 3. pHrES/SalI DNA+Ehrlich ascites S-100 extract. Lane 4. pHrES/SalI DNA+HeLa S-100 extract

run-off transcripts can be predicted from restriction analyses and sequence data¹²⁻¹⁵. None of the heterologous rDNAs yielded specific transcripts (data not shown). The inability of these DNAs to support selective transcription was not due to the presence of inhibitory components in the template preparations because they did not reduce correct transcription of the homologous mouse template in mixing experiments. Thus, although the mouse S-100 extract is capable of directing correct initiation of transcription on mouse ribosomal DNA, it seems incapable of recognizing the promoter for the ribosomal RNA transcription unit from other eukaryotic species.

The above experiments did not rule out the possibility that this apparent species specificity reflects a unique inability for promoter recognition by the mouse transcription system; extracts from other cell types might have a broader capacity to initiate correctly pre-ribosomal RNA chains. To test this, two systems derived from HeLa cells and Acanthamoeba, respectively, have been established in addition to the mouse system. In analogy to the mouse system, the human and protozoan S-100 extracts were prepared from logarithmically growing cells and were able specifically to transcribe human rDNA (pHrES) and rDNA from Acanthamoeba castellanii (pAr4), respectively (unpublished results). In the experiment shown in Fig. 1, the human and the mouse transcription system was used both with homologous and heterologous rDNA templates and in different combinations of the DNAs and the extracts. The mouse rDNA

Table 1 Specific transcription of rDNA from mouse (pMrSP) and man (pHrES) by homologous and heterologous S-100 extracts

rDNA used as		Specific
template	Source of extract	transcript*
Mouse	Ehrlich ascites (EA)	Murine
Man	EA	None
Mouse	HeLa	None
Man	HeLa	Human
Mouse	EA+HeLa	Murine
Man	EA+HeLa	Human
Mouse + man	EA	Murine
Mouse + man	HeLa	Human
Mouse + man	EA+HeLa	Murine + human

^{*}The murine transcript is a 292-base long run-off RNA from pMrSP/PvuII. The human transcript from pHrES/SalI is ~700 bases long.

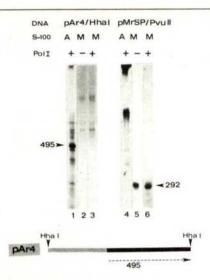

Fig. 2 In vitro transcription of rDNAs from Acanthamoeba and mouse in the presence of homologous and heterologous S-100 extracts and RNA polymerase I, respectively. A 915-base pair DNA fragment from the Acanthamoeba rDNA clone pAr4 (pAr4-Hhal) or a PvulI digest of the mouse rDNA clone pMrSP (pMrSP/PvulI) were used as templates and the transcripts analysed as described in Fig. 1 legend. S-100 extracts were obtained either from Ehrlich ascites tumour cells (M) or from log-phase A. castellanii cells (A). Reaction mixtures were supplemented (+) or not supplemented (-) with 0.015 U of Acanthamoeba RNA polymerase I purified through the heparin-Sepharose step as described elsewhere¹⁷. One unit of RNA polymerase will catalyse the incorporation of 1 nmol of UMP into RNA in 10 min in the conditions described 17. Lane 1: pAr4-HdaI DNA+A S-100 extract + RNA polymerase I. Lane 2: pAr4-HhaI DNA + MS-100 extract RNA polymerase I. Lane 3: pAr4-HhaI DNA+M S-100 extract+RNA polymerase I. Lane 4: pMrSP/PvulI DNA+A S-100 extract+RNA polymerase I. Lane 5: pMrSP/PvulI DNA+M S-100 extract-RNA polymerase I. Lane 6: pMrSP/PvuII DNA+M S-100 extract+RNA polymerase I.

clone pMrSP, when digested with PvuII at a site 292 base pairs downstream from the initiating nucleotide, yields a run-off RNA 292 bases long (ref. 15 and Fig. 1, lane 1). The human clone pHrES yields a transcript ~700 bases long after truncation with SalI (E.R. et al., manuscript in preparation, and Fig. 1, lane 4). However, when the mouse DNA (pMrSP/PvuII) is used as template in the human extract system, only low levels of nonspecific RNAs are produced (Fig. 1, lane 2). The same holds true if the human template (pHrES/SalI) is combined with the mouse S-100 components (Fig. 1, lane 3).

Mixing experiments presented in Table 1 revealed a pronounced template selectivity by the transcription factors for RNA polymerases present in the crude extracts. If both human and mouse rDNA were present in the assay, the source of S-100 determines which template is transcribed. Addition of equal amounts of extracts from human and mouse cells to a mixture of mouse and human templates results in the production of both the 292-base mouse RNA and the 700-base human run-off transcript. These results indicate that the cell-free transcription systems consisting of homologous RNA polymerase I and transcription factor(s) supplied by the S-100 extracts are only able to initiate correctly at homologous promoter sequences.

To verify this conclusion and to discover whether this apparent species specificity resides in the RNA polymerase I or the transcription factors, a third transcription system derived from A. castellanii was tested. This system yields a 495-base run-off RNA that coincides with the 5' end of 39S pre-rRNA when a HhaI-generated fragment of the Acanthamoeba ribosomal RNA repeat unit16 is transcribed in the presence of S-100 extracts from Acanthamoeba (Fig. 2, lane 1). RNA polymerase I purified from this species¹⁷ is incapable of selective transcription of this DNA in the absence of Acanthamoeba S-100 extract (Iida and M.R.P., unpublished results). Also, mouse S-100 extract yields no specific transcript with Acanthamoeba pAr4-HhaI DNA (Fig. 2, lane 2). When purified Acanthamoeba RNA polymerase I is added to mouse S-100 and used to transcribe pAr4-HhaI DNA, an increase in the 915-base 'end-to-end'

transcript but no selective transcription of pre-ribosomal RNA is observed (Fig. 2, lane 3). Supplementation of the mouse S-100 with the protozoan RNA polymerase I also does not stimulate transcription of mouse rDNA (Fig. 2, lane 6); only nonspecific RNAs increase slightly in amount. Thus, supplementation of the nonhomologous transcription factor-template mixture with homologous RNA polymerase I does not result in the synthesis of specific RNA, suggesting that the role of the transcription factor involves recognition of the promoter sequence or the polymerase or of both.

The data presented here strongly suggest that the recognition of rDNA occurs in a species-specific manner. This is in contrast to RNA polymerase II and III transcription systems, which show little or no species specificity. Comparison of nucleotide sequences in front of RNA polymerase II or within RNA polymerase III genes have revealed a remarkable sequence conservation in defined positions necessary for accurate transcription initiation 18-22. In contrast, a comparison of the sequence in the region of transcription initiation of different ribosomal genes has revealed no obvious shared consensus sequence among several eukaryotic rDNAs tested 12-15,23-25 This lack of a homologous sequence in the rRNA genes is in accord with our finding that species-specific factors are involved in the transcription of rDNA by RNA polymerase I. A change in the single promoter sequence of this transcription unit, if complemented by a similar modification of the polymerase I (or the transcription factor) DNA binding site, could be a reasonably frequent genetic variation. In addition, because the ribosomal RNA transcription unit is repeated many times per cell, genetic experimentation with altered promoter sequences may be a relatively facile (and seldom lethal) event. Apart from the constraints which might arise as a result of the need to keep the repeated genes co-evolving, genetic drift of the rRNA promoter may be comparatively rapid. Conversely, RNA polymerase II * deals with thousands of different single copy gene promoters and, because there is probably no direct mechanism to keep them co-evolving, they must remain true to the prototype TATA-box sequence to remain active.

We thank Drs R. Braun, P. Wellauer and R. Reeder for the gifts of rDNAs from Physarum polycephalum, Drosophila melanogaster and Xenopus laevis, respectively, and Dr G. Wilson for the human clone pHrES. This work was supported by grants from the Deutsche Forschungsgemeinschaft (I.G.), the NIH (GM 22580, GM 26059) and by a Senior International Fellowship (F06-TW00524) of the Fogarty International Center (NIH) to M.R.P.

Lipidic particles and cubic phase lipids

RECENTLY Sen et al. have observed1 regular arrays of inverted micelles in galactolipids and correctly depicted their molecular organization. However, the authors did not differentiate the observed inverted micelles from lipidic particles as seen in phosphatidylethanolamine and cardiolipin2-5. The inverted micelles observed by Sen et al. are, in fact, units of an inverted cubic phase first proposed by Luzzati and Reiss-Husson⁶. The inverted cubic structure has recently been observed in glucolipids by proton NMR7 and in monoglycerides by X-ray diffraction8.9. The dimensions reported by Sen et al. in galactolipids (8-9 nm) are not too different from those measured by X-ray diffraction in sunflower monoglyceride8 (5.8 nm) and in synthetic monoglycerides (4.5 nm). Unfortunately, Sen et al. did not recognize the cubic structure seen in their electron micrographs, and they did not correlate their findings with existing X-ray diffraction and NMR data of similar lipids. Instead, they compared

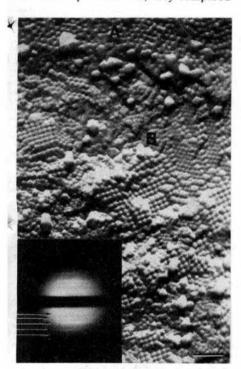

Fig. 1 Freeze-fracture electron micrograph of dilinoleoylphosphatidylethanolamine and egg phosphatidylcholine (mol ratio 85:15) dispersion. The sample was heated to 40 °C and cooled to 24 °C before being freeze-quenched in liquid propane without cryoprotectant, using the quick-freeze sandwich method13. Conical pits (lipidic particles) in area A are randomly distributed but become regularly distributed in area B, and spherical units (shadowed opposite to the pits) of a cubic structure are seen between these pits. Small-angle X-ray diffraction was taken from the same dispersion. The five reflections indicated by arrows are identified in the text. Scale bar, 100 nm.

those spherical inverted micelles with the conical 'lipid particles' seen in phospholipids2-

It is important to note that the 'particles' shown in ref. 1 are of a different nature from the 'lipidic particles' discussed previously^{2-5,10-12}. We illustrate this by showing (Fig. 1) a rapidly quenched freeze-fracture (without cryoprotectant) micrograph of mixed egg phosphatidylcholine and dilinoleoylphosphatidylethanolamine (mol ratio 15:85) at 24 °C after being heated to 40 °C. The conical lipidic particles observed in area A are the usual type of bilayer attachment observed in phosphatidylethanolamine-containing lipid mixtures. In area B, the cusps are arranged in a square array, trapping pockets of water between bilayers, thereby forming a complementary array of spheres.

These water-containing spheres, as units of an inverted cubic phase, would be truly inverted micelles were it not for their possible interconnecting water channels7,8. They should not be confused with the lipidic particles, which are the inter-bilayer attachment sites^{5,10-12} surrounding these inverted micelles. The size of the spheres is 17.8 nm in our micrograph, corresponding to our X-ray diffraction data, which show the (200), (220), (222), (422) and (440) diffractions at 8.7, 6.2, 5.1, 3.6 and 3.2 nm of a cubic structure (Fig. 1, inset). Our model for the involvement of lipidic particles in the bilayer-inverted cubic transition will be presented elsewhere.

In conclusion, we have shown that the inverted cubic phase can be observed by electron microscopy, and that this structure occurs not only in glycolipids but also in fully hydrated phospholipids. The units of the inverted cubic phase are inverted micelles, which are distinguishable in shape and size from the so-called lipidic particles or cusps.

SEN ET AL. REPLY-Hui and Boni are correct in pointing out that the term 'lipidic particle' has been used in the literature to describe a number of different structures. Unlike these authors, however, we believe these structures to be closely related.

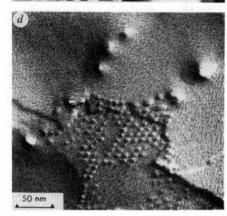

Fig. 2 Electron micrographs of freeze-fracture replicas prepared from sonicated dispersions of mono- and digalactosyldiacylglycerols mixed in a molar ratio of 2:1. a, Sample containing 58.4% ethylene glycol; b, sample containing no cryoprotectant thermally quenched from 50 °C; c, 58.4% ethylene glycol sample; d, sample containing no cryoprotectant quenched from ~20 °C. Samples were prepared and replicated as described elsewhere5

We have been able to identify at least four distinct types of lipidic particle from electron micrographs of freeze-fracture replicas of aqueous dispersions of mixed galactolipids. Figure 2 provides a composite view of some of these. The particles shown in Fig. 2a and b are regular quasicrystalline arrangements induced by the addition of ethylene glycol and by heat, respectively. Figure 2c shows isolated pits formed from particles of the type seen in Fig. 2a. A two-dimensional array of particles located within a single fracture-face is shown in Fig. 2d together with a number of rather larger particles that resemble structures attributed by some workers to inter-bilayer attachment sites1

The quasi-crystalline structures, as we pointed out in our original communication⁵, seem to correspond to aggregates of inverted lipid micelles. Hui and Boni have suggested that such structures correspond to isotropic cubic phases of a type previously reported in X-ray diffraction studies of soaps and detergents⁶ monoglycerides^{7,8}. simple In our experience, a variety of quasi-crystalline structures characterized by different particle sizes and symmetries can be induced to form in mixed galactolipid dispersions. We are, consequently, less willing than Hui and Boni to commit ourselves to any definite symmetry assignments. We do not exclude the possibility that such structures are related to cubic phases similar to those referred to by these authors but, as we have emphasized elsewhere9, more evidence based on other techniques is required before any realistic attempt can be made to analyse the detailed structure of the aggregates we have reported.

Hui and Boni further suggest that the occurrence of cusps formed by groups of pits associated with inverted lipid micelles present in these aggregates are directly related to the structures attributed to inter-bilayer attachment sites 1-4. This resemblance is in our opinion purely fortuitous and merely reflects the fact that such aggregates contain a continuous three-dimensional hydrocarbon matrix. We believe that the various types of lipidic particles reported in the literature can be accounted for in terms of a series of intermediary states made up of inverted micelles at one extreme and bilayer arrangements in which the lipids forming these micelles have been re-incorporated into the bilayer phase at the other.

This reorganization, as detailed elsewhere 10 involves an appreciable expansion of the surface area of bilayer. In the initial stages, this leads to blebs of the type seen in the fracture-face shown in Fig. 2c, and then to a buckling of the fracture-face as shown in Fig. 2d. This process can account both for the formation of tubular-micelle structures and particle-strings of the type shown in Fig. 1 of our original report⁵ and the characteristic arrangements of ridges and particlestrings reported in other studies.

Gene duplication and the birthday problem

EDLUND and Normark¹ have presented sequence and distribution data of tandem duplications of the ampC gene of Escherichia coli K-12, which suggest that recombination between unequal homologous sequences of the order of 12 base pairs (bp) in length may be a general mechanism for the generation of tandem duplications. In support of this conclusion they present calculations showing the probability of occurrence of homologies 10-14 bp long in a DNA sequence of given length. For example they state that on average two homologous sequences of any composition will be found within a random DNA sequence of 4 kilobases (kb)".

It is more realistic to calculate the length of DNA required such that the expected or average number of homologies is one. The number of homologies will be expected to be approximately Poisson distributed and the expected number of homologies, λ , will be given by

$$\lambda = n \frac{e^{-r/n}}{k!} \left(\frac{r}{n}\right)^k \tag{1}$$

where r is the length of the DNA segment, n is the number of possible different sequences of length m, equal to 4^{12} for a sequence 12 bp long, and k is the number of copies of a homology. Thus, on the average, one pair of homologous sequences 12 bp long will occur in a DNA sequence of length 5.8 kb rather than 4 kb as stated by Edlund and Normark. Allowing for the 1 kb sequence of the ampC gene, this value becomes 6.8 kb. The corrected values for Table 1 in ref. 1 may be obtained easily from equation (1).

Table 1 (ref. 1) does not make clear that the probabilities of pairs of homologous sequences are being calculated, rather than the total number of sequences which are homologous in a DNA segment of given length. Although the size of DNA required to obtain an average of four homologous pairs of length 12 bp is 11.6 kb (not allowing for the ampC gene), the length of DNA required to obtain an average of one sequence occurring four times is 580 kb! This point is significant as the opportunity for unequal recombination is much greater if multiple copies of a sequence are present than if several pairs of different sequences are present.

A further complication is that the calculation of the probability of occurrence of a sequence homology assumes that the DNA segment of length r contains r-m+1 (approximately r) independent sequences of length m. This is clearly incorrect as neighbouring sequences overlap and their probabilities of occurrence will depend on each other. If this dependency is ignored, then the frequency of sequence homologies will be overestimated.

These calculations do not alter Edlund and Normark's conclusion that unequal recombination between random homologies could be a mechanism for generating tandem duplications of the size they observe. This size, 9.8 kb, is still larger than the estimate of the minimum length of DNA required for a homology of length 12 bp to occur an average of once, even if this estimate is biased. However, the importance of such random homologies for generating tandem duplications significantly shorter in length may be questionable.

JULIAN ADAMS

Division of Biological Sciences, The University of Michigan, Ann Arbor, Michigan 48109, USA

- 1. Edlund, T. & Normark, S. Nature 292, 269-271 (1981). Feller, W. An Introduction to Probability Theory and its Applications 3rd edn (Wiley, New York, 1968).
- NORMARK REPLIES—Edlund and I recently suggested1 that unequal recombination between perfect homologies of the order of 10-14 bp may be a general mechanism for generating duplications in the size range of 10 kb. This suggestion was based on DNA sequencing of one duplication in the ampC region of the E. coli chromosome, on end point determinations of a number of duplications and on probability calculations of occurrence of homologies.

Our calculations that are questioned by Adams must be regarded as approximations. They were made in order to see whether or not our distribution of duplications could be explained by recombination betweeen short homologies of any base composition. Our calculations and Adams's do not give very different results. The main drawback with both calculations is that we do not know whether or not short homologies are distributed at random in *E. coli* DNA.

What is needed are computer scans for short homologies in continuous stretches of sequenced *E. coli* DNA. At present >5 kb has been sequenced in the *amp*C region of the *E. coli* chromosome (Yaurin and Grunchstrom, personal communication). This region is, however, still too short for such an analysis. Moreover, the recombination site for a number of independent duplications has to be DNA sequenced. Not until then will it be possible to test the calculations made by Adams and our group.

The Red Sea line and Arabian-Nubian magmatism

HARRIS AND GASS¹ suggested that the Red Sea rift developed along the line of a late Proterozoic suture and that compositional differences in the upper mantle and/or lower crust on either side of the suture controlled magmatism within the Arabian-Nubian shields during the Phanerozoic. We now discuss both the existence of the proposed late Proterozoic suture and the nature and distribution of granitic magmatism in the region.

The hypothesis that the present Red Sea rift was controlled by a late Proterozoic suture is unjustified, because it can be demonstrated that there is structural and lithological continuity from the Nubian shield segment across the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the Archive children in the Red Sea rift zone to the R

rift zone to the Arabian shield segment. Figure 1 shows a reconstruction² of the Arabian-Nubian shield before Red Sea rifting. South of latitude 20°N (all localities identified by coordinates are on the Saudi Arabian side of Fig. 1) lineaments are oriented N-S, that is, angled at between 20° and 90° to the trace of the proto Red Sea fracture. There is good lithological correspondence between rocks assigned to the Mormora, Adola, Tambian and Tsaliet stratigraphical units in Ethiopia3 and rocks assigned to the Baish, Bahah, Hali and Jiddah units in Saudi Arabia⁴⁻⁶. Radiometric age data from Saudi Arabia indicate that this distinctive lithological belt was formed between >900 and ~600 Myr ago7.

Between latitudes 20° and 24° N, northeast structural trends predominate and the basement fabric is approximately normal to the proto Red Sea fracture. Major faults and distinctive folds can be traced from north-east Ethiopia and north-east Sudan into the west-central Arabian

shield, and lithological correlations can be made between stratigraphical units such as the Nafirdeib (>750 Myr), Asoteriba (~660 Myr), Awat and Homogar of Sudan⁸ and the Samran (>760 Myr) and Fatimah (~680 Myr) of Saudi Arabia⁹.

North of latitude 24°30′N the predominant trend in the basement is northwest) and in a few places, for example, between latitudes 26° and 27°N, the basement fabric is consistent with the trace of the proto Red Sea fracture. In this region the Farri (>900 Myr), Al Ays (725–800 Myr) and Hadiyah (~670 Myr) units of Saudi Arabia¹⁰ can be lithologically matched with the Abu Ziran, Dokhan and Hammamat units of south-east Egypt^{11,12}.

The strong north-west trending basement fabric persists north of 27° N within the corridor produced by the Najd strikeslip fault system. This system traverses the proto Red Sea fracture into the Egyptian segment of the Nubian shield. In this region the Zwam Nusfat and Thalbah-Hadiyah-Shammar units of north-west Saudi Arabia¹³ are possibly equivalent to the Abu Ziran, Dokhan-Hammamat units of the central Eastern desert of Egypt.

Whilst basement structures may have locally influenced the development of the Red Sea rift it is highly improbable that the rift was fundamentally controlled by a late Proterozoic suture. Such a cryptic suture would have to traverse at least three major structural provinces in which either north-west, north-east or north-south trending structures are dominant. Furthermore, the remarkable similarity between late Proterozoic stratigraphies of countries bordering the Red Sea is incontrovertible evidence that such a suture did not exist.

Harris and Gass propose that the late Precambrian calc-alkaline granites of the Arabian shield originated in a wet mantle above a subduction zone, whereas, the peralkaline granites resulted from partial melting of dry mantle after subduction had ceased. This hypothesis does not explain why (1) in the area east and southeast of Yanbu Al Bahr, near the central Red Sea coast in the Saudi Arabian shield, peralkaline granitic plutonism occurred some 50-100 Myr before a major episode of calc-alkaline granitic plutonism (D.B.S. and J. Aleinikoff, work in progress), and (2) in general, voluminous calc-alkaline and peralkaline granitic magmas were emplaced in the northern half of the Saudi Arabian shield contemporaneously either in the same pluton^{14,15} or in the same region^{1,10,14,16}.

Finally we discuss whether the absence of undersaturated Phanerozoic magmas in the Arabian peninsula is due to fundamental differences in the chemistry of the upper mantle underlying the Nubian and Arabian shields¹. Whilst there is an apparent paucity of undersaturated Phanerozoic igneous rocks in the Arabian peninsula it is premature to say they are

absent. The undated feldspathoid bearing Sawda syenite pluton in the Midyan area¹⁷ is considered to be a possible correlative of the Egyptian nepheline syenites, and

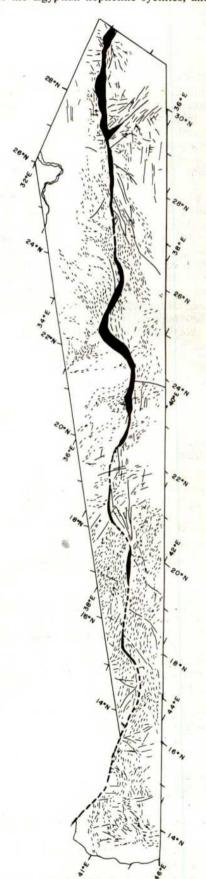

Fig. 1 Arabian-Nubian shield before Red Sea rifting.

peralkaline trachytes of unknown age puncture Palaeozoic rocks in the Tabuk area14. The chemical similarity of Cenozoic basalts in the Afar, Ethiopia¹⁸ and the Arabian peninsula 19 indicates that the mantle source region was not fundamentally different beneath the Arabian and Nubian shields.

As the Phanerozoic undersaturated alkaline magmatism in the northern Nubian shield has different character from that of the late Proterozoic Pan-African granitic magmatism, we see no reason to assume that this magmatism is an extension of the Precambrian episode. It would be more objective to say that the entire Arabian-Nubian shield experienced late Proterozoic calc-alkaline to peralkaline magmatism, and that a restricted province of predominantly undersaturated to peralkaline magmatism developed in the northern Nubian (and possibly Arabian) shield north region. Phanerozoic alkaline and peralkaline magmatism is found elsewhere in north Africa and that the Phanerozoic Nubian magmatism might be related to events in these regions.

We thank A. R. Drysdall for comments.

HARRIS AND GASS REPLY—Jackson and Stoeser have not distinguished identification between the of Phanerozoic alkaline province in northeast Africa and our speculations on possible causes of this event and its apparent absence in Arabia.

Jackson and Stoeser identify an undated svenite and trachytes from north Arabia to counter our assertion that the Red Sea marks the eastern boundary of the Phanerozoic alkaline province. Future research may discover instances of pre-30 Myr Phanerozoic magmatism in the Arabian shield, but previous work has shown that the plethora of such intrusions in north-east Africa is not present in Arabia, Current geochronological studies on samples from both sides of the Red Sea substantiate the assertion that this igneous province represents the most significant geological contrast between the two sides of the Red Sea.

Following the identification of this igneous province we gave three reasons for its eastern margin being coincident with the Red Sea whilst emphasizing that more data are needed before we can be sure which of these is most relevant. Most of Jackson and Stoeser's comments are directed against our preference for the subduction zone model.

Many have commented on the apparent continuity of structures across the Red Sea, but with coastal plains covered with late Tertiary sediments and rotation of Arabia during the opening of the Red Sea the best that can be postulated is that there seems to be, in many places, structural continuity. The lithostratigraphical correlation between Arabia, Ethiopia, Sudan and Egypt has been shown to be unconvincing even within the southern Arabia shield¹, and correlation of illdefined and regionally unknown stratigraphical units in the northern Arabian shield is highly questionable. To extend this 'correlation' across the Red Sea with no geochronological or geochemical control is misleading. For example, results from geochronological studies from several of the Egyptian units mentioned by Jackson and Stoeser are totally at variance with their "lithological matching" of Arabian units. The conclusion that there is precise correlation through the Proterozoic across the Red Sea which precludes any relative movement between north-east Africa and Arabia during late Proterozoic times cannot be substantiated by available data. However, our prime purpose was to identify the Phanerozoic alkaline province in north-east Africa. We then argued that a post-500 Myr distinction in upper mantle geochemistry across the Red Sea line seemed likely. Finally we speculated that an eastward dipping subduction zone with a surface expression along the line of the Red Sea could explain the presence of alkaline magmatism in Africa and its seeming absence in Arabia. If future studies preclude such a suture, this will indicate that the Phanerozoic alkaline province in northeast Africa is the only crustal expression of the geochemical difference in the upper mantle across the Red Sea line until the opening of the Red Sea at 30 Myr.

Jackson and Stoeser imply that the peralkaline magmatism of Arabia is part of the calc-alkaline event, and requires no change in tectonic setting. Whilst the switch from calc-alkaline to peralkaline magmatism was diachronous, the appearance of metaluminous granitoids within peralkaline complexes does not support their view as such granitoids have 'within plate' trace element characteristics (such as high Nb) and are quite distinct from the widespread homogeneous calc-alkaline plutons². Such a marked change in high field-strength element abundance requires a variation in the volatile composition of the upper mantle which could be due to a change in tectonic setting. There are several granitic provinces, such as that of Mesozoic age in Nigeria³, which lie in a within plate tectonic setting and include peralkaline and metaluminous types both with characteristic high field-strength trace-element abundances. It seems realistic therefore to use the terms 'within plate' and 'subduction zone' based on diagnostic trace element abundances, rather than the now outdated calc-alkaliperalkali classification, to identify granitoid provinces.

We believe that the contrast in Phanerozoic magmatism in north-east Africa and Arabia is well-established and the points raised by Jackson and Stoeser do not challenge this. Its relationship with earlier subduction processes suggests that contrasting mantle geochemistry may prove to be the reason and, if so, the Red Sea line was defined in the mantle (and possibly in the crust) as early as 500 Myr.

We thank R. M. Shackleton, A. C. Ries and H. J. Duyverman for comments.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should. wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

BOOK REVIEWS

Gerontology in adolescence

Alex Comfort

THE most promising omen for experimental gerontology is that it has emerged from the infancy-period of all-explaining general theories into that of specifics. The exercise is to understand and control age changes: these, in a complex organism (human beings would be the obvious beneficiaries - nobody needs long-lived mice), are bound to be multifarious. The first target is to ascertain which time-linked changes are lifespan determining, and the second to establish where, at the supragenetic level, these are coordinated. Coordinated they must be, in view of the high stability of specific lifespans and their divergence in related species.

The first two volumes of this report of a symposium convened by L'Institut de la Vie deal respectively with biology and with medicine and social science. (Volume 3, Behavioral Sciences and Conclusions, will be published later this year.) The first, gerontological, volume is an excellent introduction to the diversity of current research topics and the state-of-the-art in each. In contrast to older, one-process views of ageing, the growth stocks in current age studies are immunology, endocrinology, non-actuarial measures of the ageing process - essential, if we hope to look for interventions which modify it in organisms whose lifespans are of the same order as that of the investigator — and, over-arching these, the possibility that the peripheral changes are modulated by a neuroendocrine timekeeper. The odds are that there are some clocks running which are coordinated in this way, and others, possibly including the finitude of cellular clonal division (reviewed in this book by its discoverer Hayflick) which are autonomous.

Two excellent reviews of cerebral ageing, by Scheibel and Scheibel, and by Hachinski and Obrist, open the symposium. Immunology is reviewed by Walford, and hormones by Bierman, Adelman and Everitt — all distinguished investigators. What is lacking, though, is an integrativespeculative model. The discussion of the chances of lifespan modification, opened by the late George Sacher, is largely taken up with the potential of genetic engineering, to the exclusion of the other, and more accessible, programme store, the hypothalamus; and there is little or no consideration of the one authentic instance of age-retardation, that produced by calorie restriction in rodents, where the effect is almost certainly brain-mediated: much of the endocrinological evidence cited by Aging: A Challenge to Science and Society. Vol. 1 Biology, edited by D. Danon et al., pp.346, ISBN 0-19-261254-9; Vol. II Medicine and Social Sciences, edited by A.J.A. Gilmore, W.M. Beattie et al., pp.403, ISBN 0-19-261255-7. (Oxford University Press: 1981.) Vol. 1£25, \$59.50; Vol. II£30, \$59.50.

Adelman and Everitt points in this direction. The hypothalamus would certainly be an easier point of access than the genome, if we are undeterred by Sacher's pessimism over the social effects of success resulting in "demographic catastrophe".

That pessimism, in fact, assorts ill with the urgency of the problems raised by old age in the social and medical areas, the subject of Vol. II. Notably missing from both volumes is a full discussion of senile dementia, which, though a disease, not an "ageing effect", is now a socially ruinous epidemic and a subject of some of the most distinguished current research. There is, however, an excellent anatomical discussion by Terry in the biological section.

Perusal of the volumes leads to several conclusions - that gerontology has advanced enormously, from fringediscipline to major area of research; that in contrast to its teething years it now has more bricklayers than architects; and that possibly some of the researchers are lured by the prospects of success into long-term. genetic-engineering solutions, when they should be looking for answers nearer home which might have a more immediate clinical application. Clinical applications, not sci-fi projects aimed at radical lifespan change, are the most likely mode of entry for any results of research, and this entry cannot be stopped by social considerations, which may in any case be too alarmist.

Sacher, for example, concludes that

we should forgo our arguments about the desirability of life extension until we have done the kind of biologically-based actuarial and socioeconomic modelling that would give us at least a rough idea about the actuarial consequences of . . . life table alteration.

The hazard he envisages here — longer infirm and dependent life — seems biologically unlikely. More serious threats seem to follow from the fact that, while Vol.II of the symposium draws an excellent picture of the medical and social needs of the old under present actuarial conditions, society has so far proved resistant to providing these, and its response to longer health and longer working ability might be

equally negative and belated. A zeropopulation-growth society calls for longlived adults: having ceased to be like mice and rabbits, we might gain from becoming elephants. But, as Vol. II well illustrates, applied gerontology will undoubtedly be applied, as soon as it can be, to slowing or postponing disease changes - with the difference from current methods that the approach will probably be fundamental, and generate a whole field of ratedetermining medicine. It will, after all, probably be easier to postpone malignancy or immune failure than to reverse it once it has occurred. Examples already exist of cases in mice where diseases can be 'postponed out' of the lifespan.

This likelihood makes it extremely important to determine which of the deteriorative processes involved in the loss of homeostasis are self-timed, and which are under more general control and therefore potentially accessible *en bloc*—it is easier to change the policy of a company by tackling the chairman than by nobbling the sales representatives. On these grounds alone one may hope that an overall neurochemical "clock" will be identified.

It is, of course, possible, as Hayflick suggests, that relatively soon we may become able to address a higher level still, and make direct postnatal interventions in the genome. That would, probably, raise some policy questions, but those concerned with lifespan would be dwarfed by other and more general issues.

The most significant contributions to the second volume are Brocklehurst's discussion of training in geriatrics — a particularly urgent problem in the USA — and some short papers on geropsychiatry from the biochemical and genetic points of view. The demographic and social papers, apart from providing some menacing forecasts of what will result from continued neglect of the old, are more general, and a few, in the manner of social gerontology, verge on grannyology. Much of these may be summarized in a quotation from a notable letter to *The Sunday Times*:

I am a senior citizen [and] the following events may reasonably occur. (1) I shall have a gang of young thugs sent to paint my kitchen instead of going to prison (2) I shall have patients from the local mental hospital drafted to dig my garden (3) I may be forced to go to suitable entertainments, drink tea and wear a paper hat We . . are in a terrifying position: we are recipients. Hands off, please! I am in charge of my life.

That brief testimony should be inscribed

on the brows of the growing phalanx of "social gerontologists".

Although these proceedings are not the last word on age studies (the meeting was held four years ago and much has happened since that time) they make an excellent, authoritative and thoughtful review of the field. The papers by Hachinski and Obrist, by Scheibel and Scheibel, and by Ordy, on different aspects of brain ageing, merit reprinting where physicians will see them.

Alex Comfort is Consultant in Geriatric Psychiatry to the Veterans' Administration, Los Angeles, and an Adjunct Professor at the University of California, Los Angeles.

Search for solutions

Barbara W. Low

Structural Studies on Molecules of Biological Interest: A Volume in Honour of Dorothy Hodgkin. Edited by G. Dodson, J.P. Glusker, and D. Sayre. Pp.610. ISBN 0-19-855362-5. (Oxford University Press: 1981.) £39, \$98.

THE arts and pleasures of praise, in writing, as in reading, may be direct or oblique. This *Festschrift*, written in honour of Dorothy Hodgkin, whose seventieth birthday it celebrates, abundantly manifests these several purposes with grace and rich diversity.

There are contributions from friends, colleagues and former students. Among these latter, Dennis Riley evokes the remarkable limitations of the early laboratory in the University Museum at Oxford (almost a gaslight era), and recalls their essential irrelevance. But he remembers, as we all remember, Dorothy Hodgkin's unique gift for proposing exciting problems without obvious means of solution and the exhilaration and triumph of their solution — learning to swim by being dropped in the deep end.

The section on insulin might be the transactions of a symposium, with all the original sense of convivial atmosphere and stimulating discourse. It provides a brief but fascinating account both of early studies and of those which have followed the determination of the insulin structure in Dorothy Hodgkin's laboratory. There is a continuity of theme in the contributions from different disciplines, for all are built around the concept of structure and function. No where is this more evident than in the account by Zhang You-Shang of the Shanghai Insulin Research Group. Zhang describes the investigation, using semi-synthetic methods, of insulin activity associated with modification of the C-terminal region of the B chain. The activity of p-Ala B23 deshexapeptide insulin is neatly accounted for in terms of the Ramachandran angles of B23 Gly

(normal residue) which lie, in the Ramachandran angle plot, within the permitted region for the p-configuration.

From the contribution of the Peking Insulin Research (Structure) Group, we learn that X-ray crystal structure and solution studies of the B chain C-terminal despenta- and desheptapeptide insulins are in progress, with their promise of a closer appreciation of structure/function relationships and the relationship between binding site and active site. Mercola and Wollmer provide an illuminating example of the enhanced understanding of solution phenomena which the high-resolution study of a protein may bring. This section also includes a nice discussion by Sakabe and colleagues of hydrogen bonding in the insulin structure at 1.2 Å resolution. These contributions abord in different ways the fundamental question of intrinsic molecular flexibility or rigidity, particularly at the binding site. I also enjoyed the discussion of Falkmer and Emdem on insulin evolution and Steiner's contribution on insulin precursors.

I have chosen to write of this section in the greatest detail because it represents not only the continuity of Dorothy Hodgkin's interests, but also a continuity of theme and focus. Crystallographers will especially enjoy the methods section, which includes a discussion by Bentley and Mason of the neutron diffraction study of monoclinic lysozyme and a contribution by Isaacs on fast-Fourier least-squares refinement. The more general section on protein structure includes an account by Harrison - "Approaches to the Structure and Function of Ferritin" — a history of crystal structure studies of the virus-like iron storage protein apoferritin. She concludes this provocative contribution with a reference to the isolation of a ferritin-like protein from Azotobacter vinelandii and from E. coli. Vainshtein also spans the range of common function by describing the structure of leghaemoglobin (from Lupinus nodule extracts) and comparing it with the functionally-related myoglobin.

There are also rewards elsewhere in the book. The contributions by Glusker on the vitamin B₁₂work and by Harding on the study of gramicidin S structure both provide a lively sense of the experimentalist tackling difficult problems by persistent frontal attack and by flanking approaches, reconsidering constantly as all evidence is re-evaluated. Thus difficulties may be approached almost by stealth — the coaxing of a problem to its solution.

There are many other stimulating and pleasing contributions. But to choose was here a regrettable necessity. The editors deserve our warmest congratulations and gratitude.

Barbara W. Low is Professor of Biochemistry at Columbia University. She worked under Dorothy Hodgkin's supervision and her doctoral thesis described the X-ray crystal determination in three dimensions of potassium and rubidium penicillin.

Medicines worldwide

John Butterfield

Pharmaceuticals and Health Policy: International Perspectives on Provisions and Control of Medicines. Edited by R. Blum et al. Pp.272. ISBN 0-7099-0608-0. (Croom Helm/Holmes & Meier: 1981.) £17.95, \$37.50.

THE provision of medicines in the modern world is a complex process. It begins with the research stage; proceeds through toxicity testing and government-regulated clinical trials, drug licensing and registration; then passes into the distribution phase, which includes promotion by the manufacturers, dispensing by pharmacists and, in the case of certain medicines, prescription by the medical profession; finally it ends with consumption by patients. The beliefs and knowledge of the latter may critically affect patterns of actual drug usage in the home, a fact too often ignored by the professionals who direct the previous stages.

The authors of *Pharmaceuticals and Health Policy* collectively espouse the view that improved health care depends, in part, on the improved supply of medicines. To this end they present information about each of the key stages of the provision process and outline the various, sometimes conflicting, interests of the actors in the drama. Wisely, then, the editors have combined the skills of individuals from many disciplines — including medicine, psychology, administration, pharmacology, epidemiology, economics and sociology — and the result is an impressive amalgam of different viewpoints.

In tackling such a broad subject, the volume inevitably has its weaknesses. For example, despite the fact that readers are urged to identify themselves as "friends of research and discovery", little attempt is made to discuss the alternative forms of research management and funding which a community might adopt. Under what conditions is marked-funded, industrial research superior to state-funded, academic research? What acceptable or unacceptable "disbenefits" may be associated with each of these different modes of research support? Why have the international pharmaceutical houses been the source of so much of the pharmacological innovation of recent decades?

Similarly, despite a long essay on the individual use of medicines, no clear image emerges as to how the authors envisage consumers might be influenced to create more appropriate and productive behaviour in the field of drug usage. Personally, I would have preferred to see a more specific consideration of the needs and problems of that section of the population that conventional health education cannot reach, that is the poorer people—the people for whom education may be an anathema, who may be mentally less able

or emotionally less mature, but people who are the consumers likely to be at the greatest risk both of suffering drug-related mishaps and of not receiving suitable medication for treatable conditions. This is where health promotion must now be directed, and vigorously.

In addition, the volume does not adequately examine the consequences that national government policies have on the processes of medicine provision throughout the world. It is increasingly important that political interests are not exercised in areas such as drug registration, for example, where they could pass without the loud critical comment so often directed at academic, professional and commercial bodies.

But these cautions apart, the volume remains a worthwhile achievement. Lumbroso's essay on the introduction of new drugs and the problems faced by clinical trial organizers is of particular value. So too is Catherine Stenzl's concise chapter on the role of international organizations in medicine policy. Herxheimer and Lionel provide a sensible closing contribution on coherent policy formation, outlining the difficulties present and options open both nationally and internationally. It is with respect to the issues surrounding the latter area that the main messages of the book are to be drawn.

In the countries of the developed world, the home ground of pharmacological innovation, we have moved in the past few decades to a delicate balance between rival public, commercial, professional and governmental interests. "Structural maturity" may still not be fully established but the problems that are left are minor compared with those of 30, or even 20, years ago. In the rich world, at least, the contention that we are "reasonably well served by our drug providers" is now an entirely legitimate one.

Yet in the industrially less developed nations the situation is not so satisfactory. Not only are half or two-thirds of the people deprived of modern medication in more or less any form; but those who can obtain drugs do so in a local environment in which they may be open to many forms of harmful practice. These may be a result not only of ignorance, or lack of regulation, but also corruption — commercial, political and professional. In my view this is the central problem which drug providers throughout the world must face up to in the 1980s.

In his preface Dr T.A. Lambo, Deputy Director, WHO, says,

By my lights the reader [of this book] will be every government authority anywhere concerned with drug policy, anyone teaching clinical pharmacology, all concerned with cultural or social medicine, or medical economics, and most certainly my own

Erratum: the price of the paperback edition of *Principles of Neural Science* (reviewed in *Nature* 295, 474; 1982) is £19.95, not £25.50.

colleagues at every level who attend to international issues and collaboration in health affairs.

It certainly covers a very important subject - health policy. Those of us involved like to believe the quality of our work, of the decisions we make, the regulations we frame, the ethical motivation we achieve in the whole pharmaceutical process, are good indices of the quality of the society we seek to serve. The great trick from now on will be not simply to take care of the geese that lay the golden eggs - whether you regard those geese as the minds in the laboratory or the firms who develop and the clinicians who try the new medicines. It must also include ensuring that the eggs are safe for the children playing in the farmvard and - dare one use an old word? - that the charitable impulse of the medical and allied professions will prevail when the eggs get to the market places. All this is a complex network but there is no textbook for those involved. This slim volume will give newcomers valuable check lists based on the surveillance that the distinguished contributors have been maintaining.

Sir John Butterfield is Regius Professor of Physic at the University of Cambridge.

Great matters

Charles F. Kennel

Cosmic Plasma. By Hannes Alfvén. Pp.164. ISBN 90-277-1151-8. (Reidel:1981.) Dfl.75, \$39.50.

HANNES Alfvén's Cosmic Plasma is a highly individualistic essay about many topics central to contemporary space physics, astrophysics and cosmology. It deals with laboratory studies of cosmic plasma processes; the Earth's magnetosphere, ionosphere and aurora; Venus's magnetosphere; the solar wind and heliosphere; comets; the origin of the Solar System; interstellar clouds; cosmic rays; the question of antimatter in the Universe (to paraphrase Fermi: where is it?); quasi-stellar objects; and the expanding Universe. Alfvén's often rebelliously unconventional treatment of these topics leads him to conclude that plasma physics rules the behaviour of the Universe much more than is generally appreciated.

A basic premise of Cosmic Plasma is that our knowledge of laboratory and Solar System plasma physics must inform our understanding of more distant plasmas that we can neither manipulate nor probe in situ. To Alfvén, it is striking that spacecraft observe very different states of plasma separated by thin, stable current layers. We have learned, he says, that Solar System plasmas, and by implication all

NEW

GENETICS AND PROBABILITY IN ANIMAL BREEDING EXPERIMENTS

EARL L. GREEN

Director Emeritus of The Jackson Laboratory, Bar Harbor, Maine. Editor, Biology of the Laboratory Mouse, Second Edition.

Contents

Probability and Statistics; Segregation of Alleles; Assortment of Non-Alleles; Linkage, Recombination and Mapping; Mating Systems; Appendix 1 — Mean and Variance of a Binomial Distribution; Appendix 2 — Estimation of a Parameter by the Method of Maximum Likelihood; Appendix 3 — Extensions of the Method of Maximum Likelihood; Appendix 4 — Comparative Efficiency of Matings for Detecting and Measuring Linkage; Appendix 5 — the Fibonacci Sequence; Appendix 6 — Systems of Mating; Appendix 7 — Numbers of Mating; Appendix 8 — Nomenclature; Appendix 9 — Record Keeping; Appendix 10 — Mouseroom Layout and Procedures; Glossary of Signs; Literature Cited; Index.

This book is a primer and reference on probability, segregation, assortment, linkage and mating systems for biomedical scientists who breed and use genetically defined laboratory animals for research.

It is organised so as to be useful to 'novices' and 'experts' alike. The former will find an orderly development of the probability aspects of transmission tests, segregation analysis, allelism tests, independence tests, linkage analysis and mapping. They will see how to design genetic experiments to yield data which can be analysed and they will also find a clear exposition of the theoretical consequences of various breeding systems which will enable them to make rational choices as to the kinds of animals to use in their own research.

Experts will find that the most frequently used formulae needed for estimating various genetic parameters and their random sampling variances are assembled in tables or are clearly set forth in the text and that the extensive table of contents and detailed index will enable them to find the necessary formulae quickly.

LEVEL: Professional, graduate, undergraduate reference.

SCIENTIFIC & MEDICAL

MACMILLAN PRESS cosmic plasmas, are cellular or filamentary in structure. From this stems his astonishing conjecture about antimatter. The symmetry between matter and antimatter in the laws of elementary particle physics suggests that the Universe ought to have been created with roughly equal amounts of each. Our Solar System is made of matter, and the lack of evidence for antimatter elsewhere may mean that any primordial antimatter was annihilated when it came into contact with matter, leaving us with a matter Universe. However, Alfvén proposes that cells of matter and antimatter co-exist throughout the Universe, that the cells are kept apart by plasma forces and that annihilation is drastically slowed because it takes place only in the thin layers between cells. Antimatter is difficult to detect except by the radiation coming from its annihilation, which is much less intense than it would be if matter and antimatter were evenly distributed. We do not even know for sure, claims Alfvén, whether our nearest neighbour, a Centauri, is a star or an antistar. Annihilation, when it does occur, could provide the energy for the most violent cosmic phenomena we observe. For example, the mysterious quasi-stellars might be the result of an occasional staranti-star collision in the nucleus of an otherwise normal galaxy - if indeed a galaxy made half of antimatter is normal. And annihilation could have provided the energy for the expansion of the Universe. By weaving such (controversial) arguments, Alfvén elevates plasma physics to a position which is central to all of astrophysics.

Alfvén's track record compels us to take Cosmic Plasma seriously. He did not win his Nobel Prize for thinking the way others do. Forty years ago, he helped to create the foundations of magnetohydrodynamics. Twenty years ago, when this work had become central to space physics, he was already insisting that the most important effects occurred in thin current-carrying filaments, or sheets that separated uninteresting regions of "passive" plasma. There one would find small regions of strong electric fields parallel to the magnetic field existing in complete violation of magnetohydrodynamic theory. These electric fields were what accelerated particles to high energies in the aurora. Today we know that auroral electrons are accelerated about 5,000km above the poles of the Earth by electrostatic structures that bear Alfvén's name for them — double layers. He now asserts that the cosmic rays we observe are generated by undetectable double layers far above the poles of the Sun. The absence of antiparticles in the cosmic rays therefore does not argue against antimatter elsewhere in the Universe.

Is all of the physics presented in Cosmic Plasma correct? Many readers will find something to disagree with, just as I believe that altogether too much can be

understood assuming that cosmic rays above I MeV energy come largely from the Galaxy to accept Alfvén's Solar System origin for them uncritically. Some readers may wish to turn to Eugene Parker's excellent monograph, Cosmical Magnetic Fields (Oxford University Press, 1979), for a systematic development of the magnetohydrodynamic point of view Alfvén so thoroughly rejects. Is there another great idea or two lurking in Cosmic Plasma? It is too soon to tell. In any case, might the theoretician's cardinal sin be, not to be wrong, but to be uninteresting?

For whom is Cosmic Plasma intended? Certainly not the beginning student. It has been said that cosmic plasma theory proceeds from the cartoon approximation to the back-of-envelope approximation, and thence to detailed calculation and synthetic understanding. Alfvén believes that even our cartoons are all wrong, and so his discussion is rich in fresh cartoons. envelope calculations - and his own synthetic understanding - but is seriously lacking in the systematic development students need. One must know the literature thoroughly to follow Alfvén. Although he speaks directly to today's professionals, who can read Cosmic Plasma without a glossary, he fears they won't listen. Maybe he has tomorrow's young researchers in mind.

Alfvén's future biographers will find expressed in Cosmic Plasma his intellectual and psychological position vis à vis the conduct of science. Historians of science may perceive an interesting parallel. Just as it was given to Newton's generation to comprehend how gravity rules the Solar System, so has it been given to ours to discover and understand Solar System plasmas. Like Newton, Alfvén could not resist the temptation to contemplate the cosmic significance of what he had learned. Perhaps Alfvén's Cosmic Plasma is similar in intent to Newton's Letters to Richard Bentley. And the sentiments Newton expressed in the famous scholium to the Principia are echoed in the final lines of Cosmic Plasma:

It seems that so far no phenomena have been discovered which necessarily call for any new laws. The basic properties of a plasma seem to be the same, from the laboratory to the Hubble distance.

Charles F. Kennel is a Professor of Physics at the University of California, Los Angeles, and a member of its Institute of Geophysics and Planetary Physics.

Ten years after Moon-walking

David W. Hughes

The Moon — Our Sister Planet. By Peter H. Cadogan. Pp.391. Hbk ISBN 0-521-23684-3; pbk ISBN 0-521-28152-0. (Cambridge University Press: 1981.) Hbk £27.50, \$59.95; pbk £12.50, \$24.95.

ON DECEMBER 19, 1972, Eugene A. Cernan and Harrison H. Schmitt left the valley of Taurus-Littrow near the coast of the great frozen basaltic "sea" of Serenitatis. No one has been back to the Moon since. Twelve men wandered 90 km over its surface, spent 80 hours outside their spacecraft and brought back 381 kg of rock and soil.

Ten years on we can sit back and read about what has been learnt. Cadogan wrote his doctoral thesis on the carbon chemistry of lunar samples and worked on lunar dating after that. So we have an author who was at the sharp end of lunar research, taking time to write a book which traces our progress in understanding Earth's sister planet. Cadogan has provided us with a good, general review of the subject; a book which delves into lunar science to some depth and yet assumes no previous knowledge of mathematics or geology. He is to be congratulated on a job well done.

The book is split into six main sections. The first discusses the Moon as seen from a distance, and traces the advances in lunar cartography and geology and also the famous impact versus volcanism debate over crater formation. The second

condenses the enormous amount of information that accrued from the spate of American and Russian landers. Moon rocks and minerals are dealt with in the third section, and the next discusses the lunar soil and the way in which this is affected by the bombardment of micrometeorites, erosion by the solar wind and radiation damage inflicted by cosmic rays. Section 5 looks at the Moon as a whole and studies its shape, gravity, atmosphere, magnetism and heat sources. The final section turns to the problem of lunar origin, age and orbital evolution.

Cadogan's enthusiasm for his subject bubbles from every page, but at the same time he has taken great care to explain difficult concepts. The standard of the figures is excellent and the choice of illustrations and their positioning in the text leave nothing to be desired. The book is worth buying for the figures alone. I have, however, a minor point of criticism. Cadogan's style of English is idiosyncratic to say the least. Why should I be so generous? The style is awful. Even after 200 pages it still shocks one's sensitivity. This is not to say that the book is unreadable - in fact, I enjoyed reading it very much - but still the ghost of the illiterate scientist walks through every paragraph.

David W. Hughes is a Lecturer in Astronomy and Physics at the University of Sheffield.

AT I OUT CEME ITS

Awards

The Rank Prize Funds have announced the following awards: for Opto-Electronics, one prize worth £30,000, goes to Professor Calvin F. Quate (Stanford University, California) for his contribution to medical. biological and physical research through the concept of the scanning acoustic microscope, which uses sound rather than light to form images; the second Opto-Electronics prize of £10,000 goes to Dr Charles Eliott (Royal Signals and Radar Establishment Malvern, UK) for devising a novel infra-red detector. The Rank Prize for Nutrition is £20,000 and goes to Dr Hamish Munro (US Department of Agriculture) for his research establishing the balance of nutrients required as the body grows older.

Arthur C. Clarke (University of Moratuwa, Sri Lanka) has been chosen to receive the eighth Marconi International Fellowship Award in recognition of his scientific achievement for the benefit of humanity in the field of communications science or technology.

The Dr H.P. Heineken Prize for 1982 has been awarded to **Professor C. Weissmann** (University of Zürich) for achievement in the field of biochemistry or bio-physics.

Dr Martin D. Kamen (University of California, San Diego) is the recipient of the 1982 ASBC-Merck Award which recognizes excellence in biochemical research.

Dr Efraim Racker (Cornell University) is the recipient of the 1982 Herbert A. Sober Award for contributions to techniques in biochemical research.

Dr C.W. Daeschner Jr (University of Texas at Galveston) has been presented with the 1981 Sidney S. Kaliski Award of Merit by the Texas Pediatric Society.

The Zoological Society of London has made the following awards for contributions to zoology in 1981: The Scientific Medal to Profesor M.P. Hassell (Imperial College of Science & Technology) and Dr J.R. Krebs (Edward Grey Institute of Field Ornithology, University of Oxford); The Frink Medal for British Zoologists to Sir Eric Smith; The Thomas Henry Huxley Award to Dr N.R. Franks (University of Leeds); The Stamford Raffles Award to Lt. -Col. A.M. Emmet; The Prince Philip Prize to Jonathan Edward Greenland (The Grammar School, Bristol).

The biennial Artois-Baillet Latour Health Prize of four million Belgian francs will be awarded in 1983 for an outstanding contribution to the knowledge, the aetiopathogenesis, the diagnosis and the treatment of cancerous diseases of blood and the lymphatic system both of child and adult. Nominations to: The Secretary General, National Fund for Scientific Research rue d'Egmont 5, B-1050 Brussels before July 1982.

The International Association of Gerontology has created the Sandoz Prize for Gerontological Research. The prize, worth 20,000 Swiss Francs, will be sponsored by Sandoz Ltd. Basel/Switzerland to encourage research in all areas of gerontology and geriatric medicine including biological, medical, psychological, social and other relevant aspects with special emphasis on multidisciplinary research programs. Applications in English before 30 September 1982 to Prof. M. Bergener. Secretary General, International Association of Gerontology, Rheinische Landesklinik, Wilhelm-Griesinger-Str. 23, D-5000 Cologne 91, FRG.

Appointments

Sir Richard Bayliss is joining the Medical Services Study Group of the Royal College of Physicians of London as an assistant director.

Robert J. Beals (Hall China Co.) is to be the 84th president of the American Ceramic Society.

Sir Ralph Verney, has become a trustee of the School of Water Sciences, High Wycombe, UK.

Meetings

3-6 April, Medical Consequences of War to the Countries of Europe, Cambridge (Beer Davies, 1 Melville Rd, Edgbaston, Birmingham, UK).

5-6 April, Atherosclerosis: Mechanisms and Approaches to Therapy, London (Dr N.E. Miller, Dept of Chemical Pathology, St Thomas's Hospital Medical School, London SE1, UK).

5-7 April, Control Systems Concepts and Approaches in Clinical Medicine, Sussex (The Institute of Measurement and Control, 20 Peel St, London W8, UK).

5-7 April, The Jubilee Chemical Engineering Symposium, London (J. Ellis, IChemE, George E. Davis Building, 165-171 Railway Terrace, Rugby, UK). 5-8 April, Royal Society of Health Annual

Congress, London (Royal Society of Health, 13 Grosvenor Place, London SW1, UK).

6-7 April, Results and Potential of TMR as Diagnostic and Research Method, Oxford (Dr P. Hanley, Oxford Research Systems, Ferry Hinskey Rd, Oxford, UK).

7 April, Analysis of Surfaces and Interfaces in Electronic Devices, London (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

14-15 April, Risk, Cost and Pollution, Oxford (Mr L. Evans, Harwell Education and Training Centre, Harwell Laboratory, Oxon, UK).

14-16 April, The Assessment of Major Hazards, Manchester (Mr D.J. Hewitt, 121 Princess St, Manchester, UK).

19-21 April, 3rd International Recycling Congress, Berlin (IRC, Prof, Dr K.J. Thomé-Kozmiensky, Rhumeweg 14, D-1000 Berlin 37, FRG).

19-21 April, Cell Behaviour, London (Prof. R. Bellairs, Dept of Anatomy and Embryology, University College London, Gower St. London WC1, UK).

20-22 April, Life Sciences — Market Openings, Sheffield (A. Fraser, Frost and Sullivan Ltd, 104-112 Marlebone Lane, London W1, UK).

21 April, **Biocides in the Oil Industry**, London (Miss I.A. McCann, Institute of Petroleum, 61 New Cavendish St, London W1, UK).

27-29 April, Esarda Specialist Meeting, The Netherlands (Mr R.J.S. Harry, ECN, Postbus 1, NL-1755 ZG Petten, The Netherlands).

19-30 April, Commission for Climatology and Applications of Meteorology, Washington DC (Research and Applications Dept, World Meteorological Organization, Geneva, Switzerland).

30 April-3 May, Upper Jurassic and Cretaceous of Normandy, Le Havre (Dr J. Hancock, Dept of Geology, King's College, London WC2, UK).

30 April, Electron Beam Damage, London (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

2-5 May, Ceramics: A Space Age Technology, Cincinnati (The American Ceramic Society, Inc. 65 Ceramic Drive, Columbus, Ohio 43214, USA).

4-7 May, Secretory Immune System, New York City (The New York Academy of Sciences, 2 East 63rd Street, New York, New York, 10021, USA).

4-7 May, Council of Biology Editors, Louisville (P.L. Altman, Council of Biology Editors, Inc., 9650 Rockvill Pike, Bethesda, Maryland 20814, USA).

11 May, Transient Annealing of Semiconductors, London (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

11-13 May, ESTEC Spacecraft Electromagnetic Compatibility Seminar, Noordwijk (Mr H. Bachmann, Postbus 299, 2200 AG Noordwijk, The Netherlands).

10-14 May, Oil Pollution Control Course, Ipswich (Miss 1. McCann, Institute of Petroleum, 61 New Cavendish St, London W1, UK).

Haig and Mr Malone's successor

The State Department should think hard before appointing a successor to Mr James Malone: first, it should redefine the job.

To be appointed Assistant Secretary at the State Department with responsibility for science and technology is to be offered a poisoned chalice. Few of the recent incumbents of the post have made a success of the job. Even strong-minded people such as Dr Dixie Lee Ray (in her time a doughty environmentalist and chairman of the Atomic Energy Commission as it used to be) have failed to make a success of it. Now Mr James Malone, the conservative lawyer appointed by President Reagan a year ago, has gone (see page 187) in a cloud of speculation that his error (of omission) is that he has not succeeded in delivering the new non-Carter policy on nuclear proliferation that the President has been promising since well before his election. Although it is easy to understand how a person whose links with the nuclear industry were widely advertised to Congress at the time of the confirmation of his nomination for the post should afterwards have failed to persuade congressmen of his impartiality on proliferation issues, the chances are that Mr Malone's failure is that of a man asked to tackle an impossible job. Before Mr Malone's successor is appointed, the State Department should give some thought to his job description.

That science and technology should be represented in some tangible form in the hierarchy of the State Department now goes without saying. International relations are now too important, and too intimately linked with science and technology, to be left exclusively to diplomats. Mr Malone's continuing responsibility for representing the United States at the Law of the Sea Conference is an example of what is expected of incumbents of this post. Carrying a new non-proliferation policy through the labyrinth of the government (Congress included) is another. Although problems of arms control are formally the responsibility of the Arms Control and Disarmament Agency, no assistant secretary worth his salt could fail to have opinions on these questions (and would be counted a failure if he did not, especially when as now the head of that agency must seem to many in the State Department to be Secretary of State in waiting). But there are also important and teasing questions to be decided about technological relations between the United States and other states. Just now, Japan has people at the State Department as exercised as the Soviet Union; beating back the tide of imported electronic goods on the American market is as preoccupying as deciding what should be done about the pipeline for natural gas between the Soviet Union and Western Europe or about scientists visiting the United States from supposedly unfriendly states.

The essential difficulty of the appointment is that it requires its incumbent at once to execute important parts of the administration's policy (negotiating an agreement on the Law of the Sea that will better suit the present administration's book, for example) and at the same time to provide advice on questions that are inherently subtle and perplexing. To make things worse, the job requires its holder to be able to win friends in Congress without being able to offer domestic patronage, and yet to be able to survive in the tricky waters of diplomacy (which means more than merely remembering to say "Thank you, Mr Chairman" after even an angry intervention in a United Nations committee meeting). The underlying dilemma, for Mr Alexander Haig as well as for Mr Malone's successor, is that the executive and advisory functions of the job are not easily compatible but that the conventions of Washington suppose that no mere

assistant secretary can expect his opinions to carry weight unless he can also demonstrate that he has executive responsibility for some part of the administration's programme.

There are two common solutions to such a problem, one of which is to appoint to such an impossible job a person so eminent that he or she can neglect or delegate administrative responsibilities. The other is to support somebody with no particular expertise by a high-level advisory committee which, however infrequently it meets, includes people who can be noisy on the telephone. The more imaginative but in the long run by far the most effective solution is to seek the best of both worlds — an incumbent whose reputation will ensure that his advice is listened to, and an advisory committee that will if necessary amplify what he has to say and some mechanism for making sure that the politics (domestic and international) are attended to. The State Department, having seen successive holders of this office sink beneath the waves, must now grit its teeth for the time when science and technology must be taken seriously — really seriously.

The case of non-proliferation is a good touchstone for the appointment of Mr Malone's successor. President Carter impaled himself unnecessarily on a policy about the proliferation of nuclear weapons that seemed to non-nuclear powers a splendid illustration of the cryptic imperialism of the United States and to would-be American suppliers of nuclear equipment to be a restraint on their legitimate trade. The Reagan Administration is right to look for a better balance, one that will acknowledge that it is no more possible to outlaw the proliferation of nuclear weapons by an act of Congress than it is to repeal the second law of thermodynamics by executive order. Whether it will find such a solution will depend on its success in persuading Congress that looking for loopholes in the International Atomic Energy Agency's safeguards system is less important than finding ways of dissuading potential nuclear powers from making bombs. The trouble is that doing that is as much dependent on the oldfashioned skills of diplomacy as on what new technology has to offer. In short, the State Department should resolve to be less formal in its requirements of a policy on non-proliferation; it should appoint a successor to Mr Malone who will help it to be just that.

Uneconomic savings

The financial squeeze on British universities is to continue. Structural change is the only defence.

The British Government is nothing if not resolute in its determination to spend less on higher education. The annual forecast of public expenditure which accompanied last week's budget shows that total expenditure will continue to decline even after the academic year 1983-84 — that by which the 8.5 per cent reduction decreed at the end of 1980 will have been completed. Because all sectors of higher education are lumped together in the figures, it is not possible to tell how the continuing contraction will be shared between the universities and other kinds of institutions, the polytechnics for example. But one thing is certain — if the government's plans stick, student numbers will fall further until the proportion of young people in higher education is little more than 11 per cent. Especially when the demand for

© 1982 Macmillan Journals Ltd

higher education is increasing as quickly as at present, and when the government has itself provided for an increase in the cost of what is called "non-advanced further education" (vocational courses of various kinds), it makes no sense at all that, for the first time in British history, access to universities and to higher education in general should be restricted by decree of the Department of Education and Science.

Not even the British Government can be content with this illiberal state of affairs. Going down in history (and into a general election, now not more than two years away) with such a reputation cannot be much of a comfort. But those who will be permanently damaged are not the politicians responsible for these developments but educational institutions, universities and polytechnics, and the students whom they are now prevented from teaching. This is why it is simply not good enough that those who might be thought to be responsible for the long-term interests of the universities should for practical purposes be sitting on their hands, doing nothing to bring about the structural changes in higher education on which survival must ultimately depend. The University Grants Committee, which is technically responsible for foisting student quotas on its dependants, shows very little sign of advocating the changes in the mechanisms of financial support for universities that will be necessary if flexibility is ultimately to be achieved. The Committee of Vice-Chancellors and Principals, united (and successful) in its efforts in the past six months to establish that only the government can meet the cost of firing academics from tenured posts, is constitutionally incapable of pressing for arrangements that would encourage diversity within the university system. And the polytechnics, the other important sector of British higher education, are uncomfortably squeezed financially between local and central government yet as firmly isolated as ever from the rest of higher education. They suffer from the awkward circumstance that their bills are paid by local authorities, which are then promptly reimbursed by the central government. After two years of argument, the central government has wrested back only a token of control.

The folly of these arrangements is already clear. The student quotas to which universities are being required to plan for the academic year beginning eighteen months from now will ensure that almost all universities become smaller and thus make less efficient use of their capital equipment. Some will become so much smaller that they will be forced to abandon teaching in many fields and thus cease to be universities except in name. The obvious solution (see *Nature* 18 February, p.541) is to devise a mechanism that will enable the total cost to the government of supporting universities and their students to be defined in advance, and limited, without restricting the capacity of universities to perform the social functions of educating young people for which they were originally created. Such a device would also provide universities with an incentive towards diversity; universities fearful of their capacity to compete for students with, say, Oxbridge would be faced with the prospect either of making themselves distinctive or going out of business. Universities least able to compete would also find themselves persuaded by objective pressures to teach more economically or even to form associations among themselves whose effect would be an economical division of labour. What would be wrong with such a state of affairs except the unwillingness of individual universities to acknowledge that while they are titularly equal. some are more equal than others?

The practical obstacle to such an arrangement, however, is not so much the unwillingness of universities to acknowledge what must be done as the division between the two halves of the binary system — the universities on the one hand and the polytechnics created as a kind of academic counterforce by the late Mr Anthony Crosland in 1966. Both halves are now under severe pressure but independently. When academics are fired or teaching departments closed in either half of the binary system, it is in principle possible to ensure that the weakest will be the first to go. But there is no conceivable means by which the performance of people or departments in one half of the system can be compared with that of their equivalents in the other half. As a result, there is

every likelihood that the decisions now being made by universities and polytechnics separately are inconsistent, even nonsensical. Few among British taxpayers (many of whom are academics) dispute the need that the government should contain its public expenditure, but it is just as important that the cash limits now being enforced for higher education should be accomplished in the most economical way — that which will yield the greatest benefit for whatever funds there are to spend. After a long period during which the government has had to fight the local authorities for a measure of central control of the polytechnics, it is understandable that it should lack the stomach for trying to set up some common framework within which both kinds of institutions could function. But nothing less than that will meet the present urgent need.

Turkish illiberality

The scientific community must make up its mind how to help members denied freedom.

The sad case of Dr Yeter Ögelman (see *Nature* 25 February, p.638 and this issue, p.231), the Turkish scientist who spent more than half of last year in a Turkish gaol, is still unresolved. At the resumed hearing of her case last week, Dr Ögelman was neither acquitted nor found guilty of the charge that her part in the organization of a women's rights campaign in the early 1970s was subversive of the new social order in Turkey. The result is that the charge will remain in abeyance, allowing the authorities to breathe new life into it whenever they choose. Meanwhile, Dr Ögelman remains dismissed from her post in the physics department of Cukorova University.

What, in these circumstances, should the scientific community do? The first temptation is to protest that it is thoroughly illiberal, and a serious infringement of what has come to be considered ordinary people's rights, that a person should be hounded and imprisoned as Dr Ögelman has been. The difficulty, unfortunately, is that the scientific community is not competent to raise such a complaint. For Dr Ögelman has been prosecuted not because she is a physicist but because of her part in an organization intended to secure rights for women in a society in which these have recently been denied. So there is no cause for the scientific community or its academies to stand up and complain at Dr Ögelman's treatment. Exactly the same principle applies to other states, of which there are now all too many, in which scientists and others must work under conditions in which personal liberty is unreasonably restricted. Other people's laws may be distasteful, but they are, after all, laws from which people cannot be exempted because they are scientists.

So is there nothing that can be done for Dr Ögelman, and for the growing band of scientists imposed upon by martial law in Poland (and for that matter Argentina)? Formal protests are inappropriate — which is not to say that individuals should not be free to support other organizations that are competent to complain - but practical help is both appropriate and likely to be welcome. The obvious and shining example of what can be accomplished is that of the 1930s, when many of those for whom life had become intolerable in central Europe were able to find jobs and continue their careers in the West. Now, the plight of those whose freedom is constrained is rarely as desperate as in the years before the Second World War, and there is also something in the view that the cause of personal liberty itself will be helped if those in trouble with the authorities stay in their own countries. But the provision of refuges overseas is not the only practical help that can be offered and that is likely to be welcome. People who have lost their jobs can be helped to remain active in scientific work even from a distance. Grant-making bodies and those who organize international conferences can usefully consider the interests of their colleagues who are deprived of freedom. Is it too much to ask that the scientific community, rightly standing aloof from the internal affairs of states elsewhere, should nevertheless more systematically consider how to help those of its members who are in trouble?

Overseas science shake-up in US

Malone goes, Law of Sea again in limbo

Washington

The US State Department is carrying out a shake-up of some of its top officials responsible for international scientific and technological affairs. Last week, the department confirmed that Mr James L. Buckley, a former Republican senator who is now Under-Secretary of State for Security Assistance, Science and Technology, will become a direct assistant to Secretary of State Alexander Haig.

Mr Buckley's move coincides with the news, also confirmed by the department, that Mr James Malone is being removed from his post as Assistant Secretary of State for Oceans and International Environmental and Scientific Affairs, although he will remain head of the US delegation to the Law of the Sea negotiations which reopened in New York last week.

No official reasons have been given for the reshuffle. In the case of Mr Malone, who was previously a lawyer in private practice and had been general counsel of the Arms Control and Disarmament Agency under the Nixon Administration, sources in Washington suggest that there had recently been criticism of some of his staff appointments. It is also felt that Mr Malone had lacked sufficient time to provide adequate attention to a range of controversial policy areas for which his post is responsible.

The moves are also part of a general reorganization of the State Department which has followed the promotion of Deputy Secretary of State William Clark to the President's National Security Advisor. One result is expected to be a more pragmatic and less ideological approach to decisions involving technology and foreign policy.

The contraction of Mr Malone's responsibilities seems, in part, to be related to his failure to secure congressional backing for the proposed relaxation of restrictions on the export of nuclear technology.

Mr Malone, whose nomination to the State Department was backed by members of the right wing of the Republican party, and who has contributed to reports published by the conservative Heritage Foundation, ran into strong opposition during his nomination hearings over his previous links with the nuclear industry.

At the time it was revealed that, as a private lawyer, he had represented the nuclear industries of both Taiwan and Japan in negotiations with the United States over access to nuclear technology. He promised to distance himself from any policy decisions involving former clients, but his links with the industry raised questions about how far his efforts to reformulate the US position on nuclear non-proliferation reflected the views of the industry rather than the foreign policy interests of the nation as a whole.

Whether or not the charge was a fair one, it has limited the effectiveness with which Mr Malone has been able to argue the Administration's position. "Once his nomination had been approved, he did not help matters by producing position papers that clearly looked like industry documents," an aide to Senator John Glenn, one of the sharpest critics of Mr Reagan's efforts to boost the exports of the US nuclear industry, said last week.

Although no announcement has been

made about Mr Malone's successor, it is widely expected that several of his responsibilities for nuclear export policy will be transferred to Mr Richard Kennedy, Under-Secretary of State for Management as well as ambassador to the International Atomic Energy Authority.

Mr Kennedy was a member of the Nuclear Regulatory Commission between 1976 and 1980. Before that he served for five years on the staff of the National Security Council where he worked directly under Dr Henry Kissinger, and has therefore had wide experience of both nuclear and foreign policy.

Mr Malone's reassignment could also have an impact on the outcome of the Law of the Sea negotiations, where the United States is at the centre of two separate conflicts, on the one hand expressing its strong opposition to some of the provisions in the

European fusion sustained

Brussels

Funds to be devoted to Europe's research effort in controlled thermonuclear fusion were increased from 900 to about 1.400 million European Currency Units (1 ECU = £0.56) at a meeting of the EEC's science ministers in Brussels last week. JET, the Joint European Torus, which is being built at Culham in the United Kingdom will have a 319 million ECU budget for 1982--86 when the construction phase will be completed. European Community finance for other European fusion research has been set at 301 million ECU. This, with the contributions from national research budgets, will bring European fusion spending up to 1,400 million ECU over the next five years. The contribution from the EEC's budget for JET alone is thus increased from 195 to 319 million ECU.

In fact, most details of the fusion programme had been worked out well before the ministerial council; however, the British did their best to cut down support for general fusion research to 280 million ECU, a long way from the 325 million ECU originally requested by the European Commission, by arguing that the Commission had overestimated the speed of new developments. The European Commission calculated that 80 scientists would be needed to work on planning NET, the Next European Torus, and that accounted for much of the increased budget. But UK officials thought that because countries such as the United States or Japan were making do with 50 planners, the EEC could also do with fewer. The 301 million ECU finally agreed are supplemented by national contributions for projects involving tokamaks smaller than JET and other types of plasma confinement systems. The timetable for JET

foresees its tokamak in operation by the end of 1986.

At the press conference held by Philippe Maystadt, the Belgian science minister. who chaired the council, speculation was aroused by the omission of further international cooperation with the Soviet Union. Cooperation with Japan and the United States is to be strengthened during the new programme, he said. All four fusion "powers" are, however, cooperating with the International Atomic Energy Agency in Vienna on the Intor project, a post-JET tokamak, originally proposed by the Soviet Union. Cooperation among the Western powers is taking place simultaneously within the International Energy Agency in Paris and this may now be strengthened. The European Commission refutes the idea that an iron curtain is to be drawn across fusion research as a result of the present political tensions, since it is a field which has traditionally been kept outside East-West politics.

The meeting also approved a research programme on raw materials for 54 million ECU which covers a wide variety of different research projects including research in metals and minerals, wood, the recycling of non-ferrous metals and ceramics.

The rest of the meeting was devoted to discussing two policy papers on the reorganisation of European research cooperation resulting from the meeting held last November. Among the ideas now being given serious consideration is the setting up of a Perception and Assessment Committee, which would bring together about twenty senior members to analyse the trends of science technology and guide EEC projects to counterbalance any deficiencies.

Jasper Becker

current draft of a proposed international treaty, on the other not wishing to provoke a split with other industrialized nations which, although expressing reservations, are less inclined to reject the treaty as it now stands.

Last Thursday, the US delegation presented the conference with a list of changes that it says must be made before it will sign the treaty. These include the abandonment of efforts to place limits on the amounts of different minerals that can be retrieved from the sea bed, a revised voting procedure that would give the United States greater influence over the actions of an international authority established to regulate deep-sea mining, and dropping the requirement that US mining companies should provide Third World consortia with the latest mining equipment.

At the beginning of what is expected to be the final round of negotiations started in the early 1970s, several non-aligned countries indicated that it was too late to reopen discussion on topics which, they claimed, had been settled at earlier negotiating sessions. These countries said they would proceed with drawing up a treaty, leaving the United States to decide whether or not it wants to sign.

Behind the rhetoric, however, the real question is how far each side is prepared to compromise. A treaty without a US signature, or US financial support for the regulatory institutions which would be set up, would be of limited impact. From the American point of view, some prospective mining companies are concerned that they might be unable to raise credit from multinational banks if the treaty went ahead without a US signature, while several industrialized countries - including France, Britain and West Germany - are reluctant to jeopardize their trading relationships with Third World nations by providing too much support for the United States.

David Dickson

Polish higher education

Reform reversed

Research projects in Poland are now to be "rechecked" to assess their usefulness to the national economy, according to Dr Benon Miskiewicz, the new Minister of Science, Higher Education and Technology. Furthermore, the system for appointing assistant lecturers will be modified, and new principles worked out for the employment of graduates.

Dr Miskiewicz was addressing a meeting of lecturers from higher educational institutes subordinate to his ministry. The gathering did not include medical schools or specialist bodies such as the Mining and Metallurgy Institute of Krakow which, last September, had been a principal focus of resistance to attempts by the then minister, Mr Jerzy Nawrocki, to renege on the academic autonomy which, it had been

promised, would be incorporated into the new higher education bill. This bill, much delayed by the imposition of martial law, is now apparently undergoing redrafting and modification before going forward to the Seim (parliament).

Dr Miskiewicz's emphasis on the "usefulness" of research suggests a reemphasis of the "problem-orientated" research structure introduced in 1973 by which all research had to be associated with a specific problem of the national economy. This led to an unseemly scramble by researchers to find a "problem" rated as highly as possible by the planners. During the open press debates last summer on the future of Polish science, it was generally admitted that the "problem" structure had failed and should be replaced by some type of direct contact with industry.

By tacitly repudiating such proposals, Dr Miskiewicz was apparently trying to dissociate his ministry from such proposed reforms. During the past three months, there has been some high-level disagreement as to who was primarily responsible for the outspokenness of the academic community - the Academy of Sciences or the universities. Talking to the editorial board of the weekly magazine Polityka last January, Deputy Premier Mieczyslaw Rakowski said that the breaking point had come when the Conference of University Rectors had demanded a voice in the appointment of the Minister of Science, Higher Education and Technology. The conference, established in September 1980, was always regarded with suspicion by the government, and shortly after the declaration of martial law it was dissolved - unlike the majority of organizations which were simply suspended.

Officials of the Ministry of Science, Higher Education and Technology, however, blame the Academy of Sciences, whose institutes, they say, harboured dissidents who had been banned from university teaching. The proposed new law on the academy, which would have made the academic secretary responsible only to his fellow members and not, as at present, to the prime minister, has been abandoned. The limited autonomy which the academy has until exercised over its research budget, is likely to be reduced even further.

The authorities, however, seem unwilling to risk any further direct confrontation with the academy. A recent meeting of the presidium of the academy was addressed by Dr Hieronim Kubiak, the Communist Party spokesman on higher education, who is reputed to be the most liberal member of the Politburo. Dr Kubiak warned the academicians against pointless confrontation, stressing that the intelligentsia should "advocate a Poland which is possible". Nevertheless, he said, if there are reforms which are actually possible at present, one should support them openly and actively. Vera Rich

Industrial lure

New York

As five university presidents prepare to discuss the growing connection between universities and commercial interests in recombinant DNA research (Nature 4 March, p.1), private biotechnology firms continue to have an increasing impact. This week, two top academics decided to give up basic research posts to join private companies.

Dr Walter Gilbert, 1980 Nobel prize winner in chemistry, is to leave his American Cancer Society professorship at Harvard University as of June to retain his position as executive officer of Biogen, the Geneva- and now Cambridge-based biotechnology firm.

Dr Gilbert has had a two-year leave of absence from Harvard to fulfil his position as chairman of the board of directors of Biogen. His hopes of permanently maintaining both his laboratory at Harvard and his position at Biogen ran into unresolvable problems with the Harvard administration. He will, however, remain a senior associate of the university for two more years. His Harvard laboratory will continue to operate during this time.

His full-time commitment to Biogen comes at a time when the company's new American laboratory in Cambridge, Massachusetts has recently adopted another academic, Dr Richard Flavell from the National Institute of Medical Research at Mill Hill, as research director. Dr Flavell is officially on two-year leave of absence from Mill Hill.

Another top American academic to move into the private sector, Dr Edward Scolnick, chief of the laboratory of tumour virus genetics at the National Cancer Institute, has decided to become Merck, Sharpe and Dohme's executive director of virus and cell biology.

Michael Stein

UK budget

A gentle push

The British government's enthusiasm for new technologies, and its lack of enthusiams for the universities, was confirmed in last week's budget. While the universities can expect little respite from the austerity promised a year ago, the development of new technologies in industry is to receive a modest boost. British Telecom, which is to be allowed to increase its annual capital expenditure by a half over the next three years, is the chief beneficiary. But the Chancellor of the Exchequer has also promised the Department of Industry an extra £130 million for new technology in the next financial year, 1982-83.

British Telecom, which has recently improved its profits, will now be able to invest £2,300 million on capital projects in 1982-83, rising to nearly £3,000 million in 1984-85 mostly from its own resources.

British Telecom is now adapting its business to the liberalization announced by the government last October, the chief effect of which is to allow other companies to attach equipment to the telephone network. The government is, however, now apparently considering taking the liberalization a step further by selling off part of British Telecom. The Department of Industry would not comment last week on suggestions that a new telecommunications bill is being drafted for debate in the autumn. But ministers are discussing a document outlining several options for future telecommunications policy.

The Department of Industry is also in the throes of deciding how to spend its own windfall in last week's budget. Around £30 million of the £130 million promised for new technology projects this year will be spent on teletex, a superior type of telex. Competitors for the remaining £100 million include programmes to support the use of microprocessors in industry and research on flexible manufacturing systems, information technology and electronics.

The department's space budget, however, is likely to receive at least some of the extra money, possibly £5 million a year over the next three years. Judy Redfearn

Gene manipulation watchdog

Too smooth?

The uniquely British way of regulating research in genetic manipulation, the Genetic Manipulation Advisory Group (GMAG), may yet be a victim of its own success. The immediate difficulty is that its work seems now to have become so uncontentious that some of its sponsors and even some of its members are asking whether it should continue to exist. A decision one way or the other is likely by the end of the year, when the chairman of the group, Sir Robert Williams, and several of its members come to the end of their term of office.

Since GMAG three years ago adopted a method of qualitative risk assessment for categorizing experiments in genetic manipulation, at least its academic customers appear to have been satisfied with the informality of the procedures. Most academic work in the field appears to require only that laboratories should follow good microbiological practice or, alternatively, the lowest category of safety containment.

While notification of experiments is still legally required, this may be retrospective (in an annual report) for work carried out in open laboratories, while advance approval is no longer required for the

majority of experiments in the lowest catgegory of containment. Notifications of experiments in the second level of containment appear to amount to only about half a dozen a year.

For practical purposes, the burden of assessing the safety of experiments has been devolved from GMAG to laboratory safety committees. The bulk of GMAG's work seems now to consist of the assessment of safety arrangements in laboratories newly embarking on genetic manipulation and the drafting of guidance notes—a revised (and relaxed) procedure for dealing with manufacturing processes appeared only last week.

One substantial problem remaining is the systematic categorization of experiments involving viruses which are not covered by the regulations on the laboratory use of dangerous pathogens but which would involve hazards not now foreseen — oncogenic viruses for example. GMAG is wondering whether to set up a committee to look into this question. But the group has shied away from the field of human embryo transplants on the grounds that such work does not fall within the statutory definition of genetic manipulation and because its members do not have the necessary expertise.

Although both the Confederation of British Industry and the Trades Union Congress, which nominate members of the

group, still mutter that regulation of genetic manipulation might advantageously be transferred to the Health and Safety Executive, which has a statutory responsibility for safety at work, this view is no longer being strongly promoted.

Academic clients of GMAG, on the other hand, would prefer that responsibility should remain with the group, which has become the devil that they know. Academic investigators would also prefer that GMAG should continue in being so as to deal with whatever unforeseen problems may arise.

The most serious threat to the continued existence of GMAG seems to ennui, the lack of obvious challenge. Keeping the group alive is a modest public expense, making it a target for would-be economizers, but abolition would presumably require legislation — and parliamentary time is as scarce as money.

US electronics industry

Pooling effort

Washington

Faced with increasingly intense competition from the Japanese electronics industry, a number of large American computer companies are developing plans to pool a proportion of their research resources into a new venture, provisionally called Microelectronics and Computer Technology Enterprises (MCTE).

The idea is to achieve economies of scale for the companies, many of which invest up to 10 per cent of their annual revenues in research, by jointly funding research projects in such areas as materials science, computer-aided design, manufacturing processing and quality control.

Sixteen companies met in Florida last month to discuss plans for such a venture, which would have a research budget expected to rise eventually to about \$100 million a year. The meeting was also attended by representatives of the Department of Defense and the

UN assists India

New Delhi

The scheme developed by the United Nations Development Programme (UNDP) to encourage Indian scientists settled abroad to return to temporary work in India seems to be making progress. The TOKTEN scheme (Transfer of Know-how Through Expatriate Nationals) got under way early last year (see Nature 25 January 1981, p.343) and since then 32 Indian scientists from the United States, West Germany and Canada have visited India to work with industrial units and research institutions.

India has recently become alarmed at the extent of its "brain drain", especially among scientific personnel. Although there are no official figures, estimates place the number settled abroad at more than 100,000.

The TOKTEN scheme, already hailed as a success in Turkey, was introduced in India, with an initial contribution of \$1.1 million to encourage scientists settled abroad to give the benefit of their knowledge to their homeland. UNDP pays the fares of those who agree to visit India for a period of two or three weeks to help solve technical problems in sectors chosen by the government. The project, which is being implemented by the Council of Scientific and Industrial Research, has evoked a favourable response from both the Indian experts and the organizations with which they have worked, many of which have asked that these scientists should make a return visit or that more should come Sunil Saraf forward.

Massachusetts Institute of Technology, both of which have indicated their possible interest in collaborating with the joint research effort.

Pressure to find ways of linking the generic research needs of different companies in the computer industry has increased as the costs of research — both in real terms and as a proportion of revenues — has continued to rise.

A report published in 1979 by a panel of computer scientists established by the National Science Foundation suggested that a foundation should be established to raise funds from electronics companies and distribute them to university research departments for carrying out basic research.

As a step in this direction, the Californiabased Semiconductor Industries Association has established a Semiconductor Research Cooperative (ISRC) to act as a clearing house for companys interested in sponsoring university research. The idea of a separate foundation, however, has remained on the shelf.

Mr William Shaffer, spokesman for the Control Data Corporation which organized the Florida meeting, said last week that the ISRC initiative did not go far enough for the industry and was more limited in scope than the proposal which was discussed in Florida which would embrace not only a range of research activities designed to enhance the production of electronics and semiconductor components — an area in which the United States has lost considerable ground to Japan in recent years — but also provide training and other kinds of assistance to collaborating companies.

Computer manufacturers present at the meeting included Burroughs Corporation, Digital Equipment Corporation, Honeywell Incorporated, Sperry Corporation and Rand Corporation. Among the semiconductor producers were Advanced Micro Devices Incorporated. IBM had been invited to participate but did not attend.

The companies agreed to a general framework for a joint research venture that would embrace both basic and applied research. Such a joint venture will have to avoid conflict with strict American anti-trust laws, which have previously been quoted as a major impediment to collaborative research between different companies in the same industry. The need to "clarify" the application of anti-trust laws to research was one conclusion of an eighteen-month review of domestic policies affecting technological innovation carried out under President Carter; a subsequent report from the Department of Justice, published in November 1980, concluded that "in general, the closer the joint activity is to the basic research end of the research spectrum . . . the more likely it is to be acceptable under the anti-trust laws".

Control Data Corporation says that the outline of its proposals already presented

to the Federal Trade Commission has not met with any objections. The company is hoping that, by stressing the intention of MCTE to carry out research rather than produce electronics components, any potential conflict with the anti-trust laws will be minimized. **David Dickson**

UK-Romania cooperation

One-way street

Ruchares

The meeting earlier this month of the UK-Romanian Joint Commission on Trade and Technology produced a novel suggestion from the Romanian delegation: the establishment of long-term joint technological research projects. But the suggestion is unlikely to stimulate a positive response from the British side, since attempts at cooperation over the past decade have almost all become bogged down in bureaucracy and delay.

Even the one moderately viable project—the production under licence in Romania of BAC-111 aircraft—has run into difficulties; and hopes that the finished product might be exhibited at this year's Farnborough air show are rapidly fading.

Joint research and development ventures are impeded not simply by the currency problems endemic in all dealings with Eastern Europe but also by the reorganization of Romanian science during the seventies which has been specifically aimed at eliminating dependence on foreign licences and the development of a native technological base. According to Romanian planners, during the past five years, Romanian research has provided some 90 per cent of the new materials and more than 90 per cent of the new technologies put into production. This appears to leave little room for technological flow and exchange.

Romanian-British cooperation is formally of two kinds. Pure research, including exchange scholarships, is handled by an agreement between the Royal Society and the Academy of Romania. The restructuring of Romanian science has, however, reduced the academy's role.

The driving force in Romanian science is now the National Council for Science and Technology, headed by Dr Elena Ceaucescu, wife of the president, and the main research potential is concentrated in ten "Central Research Institutes" whose emphasis is largely on applications. At the height of the reforms, in the mid-1970s, it seemed that fundamental research might vanish altogether in Romania; now, however, 10 per cent of the science budget is allotted to "fundamental research".

Although at the academic level it has been possible over the past few years to arrange some cooperation projects — such as the exchange agreement between the Polytechnic University of Bucharest and the Polytechnic of Central London, the types of programmes that would normally fall within the competence of the joint commission are considerably harder to arrange. A joint seminar, held in Bucharest last May, on problems of energy saving in agriculture was — from the Romanian point of view — highly successful, but the British side is reluctant about a return visit, since they felt the "pooling" of knowledge came almost entirely from the British side.

Romanians involved in such ventures admit the disparity. But such one-side arrangements can never prove satisfactory in the long term to the "donor" partner, particularly when all procedural matters are hamstrung by bureaucracy. For, according to a law of 1974, any Romanian scientist contacted by a foreigner must report the matter to the relevant ministry. Although a number of prominent scientists say this regulation is a dead letter, the atmosphere of delay and obfuscation is hardly conducive to international cooperation.

Vera Rich

Bio-fund open

Those wishing to take advantage of the European Community's offer to support research and training in biomolecular engineering should think fast. Applications for research contracts are needed by 15 May, and for training contracts by July.

After a long and arduous gestation period, the EEC sponsorship of biomolecular engineering was looked on as something of a disappointment — "we came out with a mouse", said Vicomte Etienne Davignon, commissioner for research and development in Brussels (Nature 28 January, p.273).

But for all that, there is about 8 million European Currency Units (£4.5 million) available, and in the United Kingdom the Department of Industry shows signs of being anxious to alert UK scientists to the possibilities of obtaining EEC support for their work.

Research contracts are available for projects mainly related to agriculture and the safety of genetically manipulated organisms. Training contracts lasting 1 to 2 years from January 1983 cover a wider range of subjects including the development of cloning systems and gene transfer in agriculturally important plants. The commission invites submissions from "employed scientists (including those employed by industries) or unemployed scientists (who recently completed a doctoral thesis or postdoctoral assignment) who have demonstrated their capacity for high level scientific research". Applicants should approach the European Commission, but the Department of Industry will advise UK scientists how to apply. Charles Wenz

Congress tackles 1983 budget

Close vote on science budget a surprise

Washington

In the first congressional action on the research and development budget for the fiscal year 1983 submitted by President Reagan at the beginning of February, a subcommittee of the House of Representatives Science and Technology Committee agreed by one vote last Thursday to recommend that the budget for the National Science Foundation (NSF) be increased by \$30 million over the President's request to a total of \$1,099.5 million.

The subcommittee left untouched the proposal to spend \$1,052.3 million on "research and related activities" sponsored by NSF, although it has suggested some reshuffling between categories. For example, it suggests cutting from 9.5 to 5.6 per cent the proposed increase in funding for mathematical and physical sciences, and that biological, behavioural and social sciences should grow by 14.2 rather than 6 per cent, particularly in the light of the major cuts in social science research last year.

The subcommittee has also proposed transferring some of the funds for research to support the International Institute for Applied Systems Analysis in Vienna. However, the Reagan Administration's decision to eliminate its contribution to the institute, originally taken last year but since reconsidered, is said to have been made final at a meeting of the National Security Council last week.

The main difference between the subcommittee's and the Administration's proposals are over NSF support for science education. Whereas the Reagan Administration, committed to phasing out such activities within NSF, has proposed a budget of \$15.0 million in 1983 — down from \$70.7 million in 1981 — the members of the subcommittee have registered their opposition by adding another \$30 million.

It was primarily this decision that led the Republican members of the subcommittee, as well as newly-elected Democrat Dave McCurdy of Oklahoma, to vote against the proposed increases. Disagreement over the science funds is also expected to generate another close vote in the full science committee when the budget authorization bill comes up for approval.

The closeness of the vote, especially among the members of what is generally considered to be one of the most proscience subcommittees in Congress, suggests that the final figures for government support of research and development

next year are likely to be close to those submitted by President Reagan, since Democrats seem reluctant to ask for major increases in the science budget and Republicans are reluctant to demand major decreases.

According to a preliminary analysis of the Administration's budget request released last week by the American Association for the Advancement of Science (AAAS), the net result of the request would be to increase research and development spending by 2.2 per cent in real terms over 1981 to \$44,400 million.

Within this total, basic research will increase from \$5,100 million in 1981 to \$5,900 million in 1983, an increase of 14.9 per cent in current dollars, but a decrease of 1.3 per cent in constant dollars. The AAAS analysis demonstrates clearly that the expansion of research budgets is almost entirely explained by the growth of military-supported research.

Much grousing has been heard on Capitol Hill over the past few weeks as different committees have held hearings on the Administration's proposed budget. Some of the loudest have come from members of the space science community where, although major projects such as the Galileo mission to Jupiter have retained support in an overall budget that increases by 28 per cent between 1981 and 1983, several research programmes will still have to be terminated.

Quoting examples such as the decision to close the lunar curatorial facility, the main centre for the analysis of Moon samples and cosmic dust collected by the Apollo missions, as well as to shut down the transmission and reception of data from Pioneers 10 and 11, launched in the mid-1970s and still sending data from deep space, the planetary sciences division of the American Astronomical Society has released a statement claiming that the Reagan budget would devastate planetary research at the National Aeronautics and Space Agency.

A strong critic of the Administration's proposals for energy research has been Dr John Deutch, who was director of the Department of Energy's Office of Energy Research for the first two years of the Carter Administration, and is now dean of science at the Massachusetts Institute of Technology. Dr Deutch told a Senate subcommittee last week that the proposed cuts in energy research and development supported by the federal government would have a damaging effect on the nation's future energy supply. The private sector could not be expected to undertake all necessary research and development in energy, said Dr Deutch: "a policy based on this assumption places our technical future in energy technology at risk".

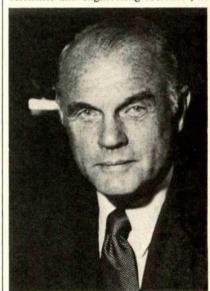

Whereas the Administration is planning to cut support for coal research and development from \$500 million in 1982 to \$84 million next year, Dr Deutch suggested it should be raised to \$625 million. In contrast, rather than asking for \$557 million for the support of breeder reactor systems research, he suggested cutting this back by \$125 million and abandoning the proposed liquid metal fast breeder reactor at Clinch River in Tennessee, which he described as "unneeded and technically obsolete".

The most important factor determining the final outcome of the science budget will be the broader political debate on how much of a federal deficit the nation's economy can tolerate. If Congress decides that the proposed deficit is too large, but is reluctant to cut back on demands for increased military spending (or to increase tax revenues), then it will be looking for more cuts in the civilian budget. Whether this will be necessary depends on deliberations within the budget committees of the Senate and the House of Representatives that will be taking place over the next two David Dickson months.

Glenn speaks out

One of the strongest critics of the Administration's policies towards the support of research and development is Senator John Glenn of Ohio who, like Senator Harrison (Jack) Schmitt, the chairman of the Commerce Committee's science and technology subcommittee, was a member of NASA's early astronaut team.

Senator Glenn has been addressing scientific and engineering societies, in

Glenn - from spaceship to White House?

particular advocating strong unilateral measures to prevent the proliferation of nuclear weapons through controls on nuclear exports. He is also expected to be a candidate for the Democrat presidential nomination in 1984, offering an alternative vision of liberalism to those of Senator Edward Kennedy and former vice-president Walter Mondale.

Professional pride

SIR — On page 542 of your issue of 18 February you inveigh against the "deceit" of groups of professional people who combine to campaign against nuclear weapons. On page 545 we read ". . . the Pentagon's Defense Science Board, chaired by Dr John Deutsch of the Massachusetts Institute of Technology. recommended a start on the production of binary weapons and that the Department of Defense should prepare for a major increase in its chemical warfare programmes". I do not recall having seen in your editorial columns any denunciation of this kind of professional activity. Apparently it is all right for groups of bought scientists, operating mainly in secret, to promote the development of the instruments of mass murder, but somehow deceitful for groups of free scientists, meeting in public, to take the contrary stance.

J.R.S. FINCHAM

Department of Genetics, University of Edinburgh, Edinburgh, UK

Protein evolution

SIR — Hoyle and Wickramasinghe believe, probably correctly, that the age of the Earth is not great enough to have given time for chance mutations to produce enzymes specified at every point in a chain of, say, 200 amino acid units. Jukes (Nature 18 February 1982, p.548) replies that proteins evolve by elongation of small polypeptides. This reply is insufficient if the elongation process must still produce a unique arrangement of amino acid units of the chain length of the final enzyme.

The size of the initial polypeptide is irrelevant. The essential point is (see also Nature 3 December 1981, p.396) that enzymatic activity of a particular kind can arise from quite short lengths of polypeptide chain, for example six amino acid units. The rest of the chain, if present, may gain significance in the course of evolution, and must certainly have the property of not folding so as to enclose the active part of the chain. The presence of life on this planet does not, however, depend, as Hoyle supposes, on the emergence of the complete chain, specified point by point. The minimal length required for a particular enzymatic activity would not require Hoyle's endless aeons to appear by chance; it would be already present in the primitive ocean. A.E. ROUT British National Oil Corporation

(Trading) Ltd, London W1, UK

A wing and a prayer

Sig — Is Jukes a secret believer, or merely an unwary fox in among the fundamentalist chickens? The ancestral relationship he implies between the biplane and the Boeing 747 (Nature 18 February, p.548) is one of design, not of descent. This is a striking counterpart of the creation process. Tragically, God's Concorde has fallen a long way since his maiden bite at the evolutionary tree, and even American jumbos finally land up in (we hope) US junkyards. Pigs might, but they have the good sense not to try. C. DARNBROUGH The University of Glasgow, Glasgow, UK

Electricity costs

Sir - Professor Fremlin (Nature 1 October 1981, p.332) wonders why the retail price index is used to correct for inflation. The short answer is given by the Central Electricity Generating Board's (CEGB's) 1980-81 report, paragraph 168. "The cost per kWh of fuel. rose by 18.6 per cent (between 1979-80 and 1980-81). This was higher than the general inflation rate (a 16.3 per cent increase in the RPI) for a number of reasons". RPI is used almost universally as a measure of the general inflation rate. It also favours nuclear costs.

I have previously dealt1 fully with the question of interest rates for comparison purposes, and if Professor Fremlin wants to discover an investment giving a steady 5 per cent above inflation rate I suggest he keeps an eye on his electricity bills, because they will have to cover a real 5 per cent interest on the funds being built up for decommissioning etc., by CEGB.

As far as accuracy is concerned, CEGB cost figures are given to 1 in 10,000, so my 1 per cent accuracy in the tables of my letter (see Nature 27 August 1981, p.791) hardly requires a probable error. Where "estimated minimum (or probable) corrections" are given, the 'error'' arises from the refusal to release available accurate information and its magnitude is known only to CEGB.

On future action, until Professor Fremlin is prepared to take real account of the work of Gerald Leach and his colleagues2, I cannot take seriously such ex cathedra statements as his last sentence, "As of now it (nuclear power) is the only means capable of the scale of output needed".

I accept that cost ratios in 25 years' time are far more uncertain that the differences between my figures and those of CEGB. (Although it seems that there is considerably more uncertainty on nuclear than on coal costs.) The importance of the calculations of present costs is that CEGB claimed to be able to produce cheaper electricity by building new nuclear power stations immediately (Heysham II and the Sizewell PWR) even though they were not needed to satisfy demand. It has now been demonstrated1 that this claim was entirely dependent on the assumption of a massive (36 per cent) increase in the real cost of coal to CEGB over the six years of the construction period (1980-86). This assumption was very effectively camouflaged in the board's documents and this is not surprising since it was made at almost exactly the same time as the "understanding" was entered into with the National Coal Board which practically guarantees that the real cost of coal to CEGB will not rise at all between 1980 and 1985.

In that case building Heysham II will certainly result in dearer electricity than if it had not been built, but instead the large overcapacity of coal-fired stations, which are at present being prematurely retired, had continued in operation.

Building unnecessary expensive new power stations may not bankrupt CEGB, but it will not help industry get cheaper electricity.

PCBs in rice oil

Sig — In March 1979, patients suffering from chloracne began appearing on the west coast of Taiwan. By October the disease had reached epidemic proportions, affecting over 1,100 people in the T'aichung and Changhua prefectures.

The exposure factor common to these patients was the consumption of rice oil produced by the same rice oil processing company situated in Changhua prefecture. Investigation of the manufacturing process identified a leak in a heat exchanger, which resulted in oil contamination with Kanechlor 400, a 48 per cent chlorinated biphenyl. In addition to symptoms associated with chloracne, clinical signs included respiratory symptoms, decrease in conduction velocity in peripheral sensory nerves, diminished growth in young children, and four reported cases of pigmented skin in newborns, all of whom died within a year of birth.

The same type of mass rice oil contamination was reported in western Japan in 19681, affecting more than one thousand victims. These were cases of direct consumption of high doses of polychlorinated biphenyls. The use of these substances was banned in Taiwan in 1972, but that did not prevent this recurrence, which is evidence that Kanechlor 400 is still being used in the heat exchange process during the production of oil for human consumption. This recurrence should serve as a warning to those Asiatic riceproducing countries which still use these oil production systems.

Holmes' lives on

SIR - What's this nonsense about Holmes' Principles of Physical Geology being "long out of print"? ("What Makes a Good Textbook"; Nature 11 February, p.459.) This work has never been out of print. A comprehensively revised third edition was prepared by Sir Arthur's widow Doris (herself a fine geologist in her own right) and published in a revised format in 1978. The book has, as you say, been a great success both critically and commercially. It continues to be so after nearly 40 years of uninterrupted availability. DOMINIC RECALDIN Thomas Nelson & Sons Ltd, Walton-on-Thames, Surrey, UK

An end to creation?

SiR — Why do you continue to publish letters on creationism? I am reasonably confident that you would not publish arguments on whether the Earth is flat or whether epilepsy is caused by demoniacal possession.

Of course, scientists are entitled to their private superstitions; but they have no place in a supposedly serious journal. Pray let us see those long overdue words: "This correspondence is now closed.'

Science on the Space Shuttle

W.M. Neupert, P.M. Banks, G.E. Brueckner, E.G. Chipman, J. Cowles, J.A.M McDonnell, R. Novick, S. Ollendorf, S.D. Shawhan, J.J. Triolo & J.L. Weinberg

THE third flight of the Space Shuttle, chiefly intended to test the orbiting portion of the Shuttle in extreme thermal conditions in space, nevertheless carries a scientific payload. The investigations will demonstrate the Shuttle's capability for research in space plasma physics, solar physics, astronomy, life sciences and technology and will also determine the effects that the presence of the Orbiter may have on its immediate environment. The information to be gathered is thus the foundation for planning of future investigations with the Space Shuttle.

The scientific payload is designated OSS-1 because the programme was originally managed by the Office of Space Science (now the Office of Space Science and Applications) at NASA headquarters. Responsibility for development of the payload was assigned to the Goddard Space Flight Center. The manager for the scientific payload is Kenneth Kissin. The OSS-1 instruments will study the Orbiter's plasma environment and the propagation of an electron beam in space, record the Sun's UV and X-ray fluxes, observe the zodiacal light and Milky Way, record interplanetary dust particle impacts, operate a sophisticated heat pipe system and also grow plants in the Orbiter's cabin. Demonstrating the Orbiter's research capability demands accurate control of the Orbiter's orientation during solar observations and use of a Remote Manipulator System to carry a package of sensors that will map charged particle and

Werner Neupert is OSS-1 Mission Scientist and Head of the Solar Plasmas Branch, Laboratory for Astronomy and Solar Physics, at NASA Goddard Space Flight Center, Greenbelt, Maryland; Peter Banks, Principal Investigator of the Vehicle Charging and Potential Experiment, is Adjunct Professor Physics at Utah State University, Logan, Utah, and Professor of Electrical Engineering at Stanford University, Stanford, California; Guenter Brueckner, Principal Investigator of the Solar Ultraviolet Irradiance Monitor, is Head of the Solar Physics Branch at the Naval Research Laboratory, Washington DC; Eric Chipman is Program Scientist for the OSS-1 mission at NASA Headquarters, Washington DC; Joe Cowles, Principal Investigator of the Plant Lignification Experiment is Professor of Biology, University of Houston, Houston, Texas; J.A.M. McDonnell is Principal Investigator of the Microfoil Abrasion Experiment and Reader in Space Sciences at the University of Kent, Canterbury, UK; Robert Novick, Principal Investigator of the Solar Flare X-ray Polarimeter, is Professor of Physics, Columbia University, New York; Stanford Ollendorf, Principal Investigator of the Thermal Canister Experiment is Head, Spacecraft Component Development and Analysis Section, Goddard Space Flight Center; Stanley Shawhan, Principal Investigator of the Plasma Diagnostics Package, is Professor of Physics, University of Iowa, Iowa City, lowa; Jack Triolo, Principal Investigator of the Con tamination Monitor Package is in the Spacecraft Component Development and Analysis Section, Goddard Space Flight Center, Greenbelt, Maryland; and J.L. Weinberg, Principal Investigator of the Shuttle Spacelab Induced Atmospheres Experiment, is Research Scientist and Director of the Space Astronomy Laboratory at the University of Florida, Gainesville, Florida.

magnetic and electric field distributions around the vehicle.

The same instruments will make sensitive measurements of how the Orbiter alters its environments by the emission of particles or electromagnetic fields. Although the spacecraft has been designed to minimize such effects some, such as propellant plumes from thruster engine firings or electromagnetic radiation from the electrical circuits, are unavoidable.

physical conditions that led to the formation of the aurorae, seen at high latitudes!

The Vehicle Charging and Potential Experiment is the first opportunity to make vehicle charging and electron beam studies from a manned spacecraft. In the first instance, measurements will be made of the effect of the natural ionospheric environment on the gross electrical characteristics of the Orbiter using two pairs of charge and current probes, situated on opposite corners of the pallet, which simulate both the electrically insulating and conducting portions of the Orbiter's surface, and with a Langmuir Probe-Spherical Retarding Potential Analyser located on the sill of the pallet.

Active electron emissions will be used to change the natural electrical balance to

The nine instrument packages on the third Shuttle flight should yield important data for space plasma physicists, astronomers, life scientists and engineers and also pave the way for future scientific payloads.

All but one of the OSS-1 instruments are mounted on an engineering model of the Spacelab pallet manufactured by the European Space Agency (Fig. 1). The instruments, pallet and the various subsystems for command, data handling, power and thermal control weigh 3,132 kg. The Plant Lignification Experiment is located in mid-deck lockers of the Orbiter cabin and two OSS-1 tape recorders and two control panels are located in the aft flight deck on the upper level of the cabin. Most internal experiment operations will be carried out via commands from the investigators located at the Payload Operations Control Center at Johnson Space Center in Houston, Texas.

On the third Shuttle flight, scheduled for late March, the Orbiter will be placed in a circular orbit of 241 km with an inclination of 38°. During the seven-day flight, the Orbiter will be held in several attitudes as part of the mission's thermal test objectives. The 28-hour long orientation of the Orbiter bay towards the Sun is suitable for solar observations. The planned 80-hour long period when the Orbiter will be maintained with its nose towards the Sun is a prime observing interval for the plasma physics investigations.

The nine experiments will now be described separately.

Electromagnetic environment

During the next decade, active electron and ion beam experiments in space will become an important tool for probing the environment above the Earth's atmosphere. This region contains plasma and magnetic fields of both solar and terrestrial origin. Hitherto, actively controlled charged particle experiments carried by rockets and unmanned satellites have been used to probe the structure of the Earth's magnetic field and to create the

determine how a charged Orbiter will affect electron beam and direct plasma measurements. The electron source (the Fast Pulse Electron Generator) emits a 100-mA beam of nearly monoenergetic 1 keV electrons. Pulses as short as 600 ns or as long as 109 s can be generated (Fig. 2a).

The Fast Pulse Electron Generator will also be used to investigate the effectiveness

of generating electromagnetic radiation by pulsing the electron beam at frequencies as high as 1 MHz. Several ground-based observatories will attempt to receive this radiation. Of particular interest is the extent to which VLF radiation can be generated using special electron beam modulation sequences. Detection will be attempted both at ground observatories and with VLF receivers aboard the recently launched Dynamics Explorer satellites.

Evidence will also be sought for a laboratory phenomenon termed beamplasma discharge, in which an electron beam energizes a plasma column which then emits intense optical radiation and radio waves (Fig. 2a). It is thought that the electron beam initially ionizes residual gas, producing a columnar plasma. As the plasma density builds up, the beam creates electrostatic plasma waves which impart additional energy to the plasma, leading to further ionization and excitation and causing the column to emit optical and radio waves. In Earth-orbit, the different conditions may mean that beam plasma discharge does not occur - the gas density is less, the beam is not terminated by the metallic top of a chamber and the Orbiter moves the beam across magnetic field lines so that plasma may not build up. The Vehicle Charging and Potential Experiment will be used with the Plasma Diagnostics Package to tell whether beam plasma discharge is initiated by the beam from the orbiting electron generator (Fig. 26).

Ionosphere studies

The Earth's ionosphere can be studied by introducing perturbations such as chemical tracers, radio waves and particle beams and by creating plasma wakes around solid bodies. The objectives of the Plasma Diagnostics Package, an assembly of electromagnetic and particle sensors, are to assess the electromagnetic and plasma environment of the Orbiter, to study the interaction of the vehicle with the surrounding plasma, to test the capabilities

of the Remote Manipulator System and to carry out active beam-plasma experiments in conjunction with the Fast Pulse Electron Generator. Measurements will be made of electric and magnetic fields, plasma waves, energetic ions and electrons and plasma parameters — density, composition, temperature and directed velocity (see Table 1).

The Plasma Diagnostics Package will be operated both on the OSS-1 pallet and while deployed by the Remote Manipulator System. As the Plasma Diagnostics Package is moved in and around the Orbiter bay, measurements will be made of the ambient pressure and of the spectrum of electromagnetic interference generated by the Orbiter's electrical subsystems. The pressure profiles in time and in distance from the Orbiter are relevant for the design of instruments sensitive to gaseous contamination and those requiring low operating pressures. The sensitivity of wave receivers and of topside ionospheric sounders to be flown on future Spacelabs will be determined by the levels now measured, while measurements of electric fields and particles by the Plasma Diagnostics Package will provide an independent assessment of the charge condition of the Orbiter.

The Orbiter will move in the ionosphere, at supersonic velocity (Mach number 6 relative to the characteristic plasma sound speed or the ion acoustic sound speed2) and so will create a plasma wake that may be identified by plasma depletion, energization of particles and the creation of Alfven waves behind the Orbiter. Such processes are thought to be important consequences of the motion of other bodies through plasmas - for example, Alfvèn waves behind the jovian moon lo may accelerate the particles which cause decametric radio noise bursts3. Remote Manipulator System trajectories have been designed to move the Plasma Diagnostics Package through the wake boundary, thus providing direct observations of its Physical properties. When the package

flies again on the Spacelab-2 mission as a subsatellite, the wake will be examined out to 20 km behind the Orbiter⁴.

The combination of the Fast Pulse Electron Generator and the Plasma Diagnostics Package provides an opportunity to study the interactions of a beam of accelerated electrons with the ambient space environment (see Fig. 2b). Radio waves over a wide frequency range may be stimulated by both pulsed and continuous operation of the electron beam and measured with the Plasma Diagnostics Package. The two instruments will also operate together to investigate beamplasma interactions such as the beam plasma discharge. Similar experiments will be conducted with more intense beams on Spacelab-1 and on later missions5.

Solar ultraviolet radiation

Solar UV radiation in the spectral range 120-300 nm has an important role in the energy balance and photochemistry of the Earth's upper atmosphere. Molecular oxygen absorbs radiation at wavelengths below 242 nm, resulting in its dissociation into atomic oxygen; ozone is dissociated into molecular and atomic oxygen by UV radiation below 310 nm. These reactions

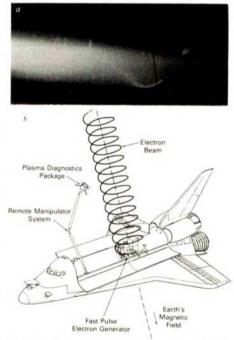

Fig. 2a, Photograph of light emission resulting from the interaction of electrons generated by Fast Pulse Electron Generator with residual atmosphere in a space simulation chamber at the Johnson Space Center. The column of luminosity enclosing the helical path of the primary electron beam is due to the occurrence of a beam plasma discharge for the conditions pertaining to this particular operation of the electron generator. b, Scheme for the joint Fast Pulse Electron Generator and Plasma Diagnostics Package operations. As the electron beam is emitted along some angle to the Earth's magnetic field, the Remote Manipulator System sweeps the Plasma Diagnostics Package back and forth across the beam region to make measurements of plasma fields and waves and of the energy distributions of electrons and ions.

take place at altitudes from 30 to 160 km in the Earth's atmosphere. Ozone is formed from molecular and atomic oxygen by a catalytic reaction which involves trace species such as NO, NO, or Cl. Quantitative description of these reactions requires precise knowledge of the absolute amount of solar UV radiation as a function of wavelength. Although many attempts have been made to measure this quantity, large experimental discrepancies still exist⁶ (Fig. 3). The objective of this first flight of the Solar Ultraviolet Spectral Irradiance Monitor experiment is to establish a more accurate base of solar UV irradiance measurements with an absolute error of 10 per cent or less over the wavelength region 120-400 nm. During the STS-3 flight, it will accumulate approximately 20 hours of solar measurements, compared with 5 minutes during a typical sounding rocket flight.

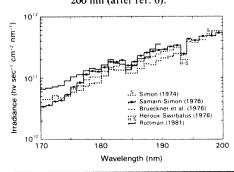

Calibration is important. The instrument carries two independent spectrometers and an in-flight calibration light source which allows tracking of any sensitivity change due to vibration at liftoff or contamination during flight. Its seven detectors will allow cross-checks of possible detector changes. It can be operated in broadband (5 nm) or narrow band (0.15 nm) modes over the wavelength region 120-400 nm. During 17 orbits amounting to approximately 28 hours, the bay of the Orbiter will be pointed to the Sun by the crew, using Sun sensors mounted on the Solar Ultraviolet Irradiance Monitor and measurements of solar intensities will be interleaved with periodic in-flight calibrations7.

The measurement of the solar UV irradiance on OSS-1 is only the first step of a programme to measure the variability of the solar UV radiation over an 11-year solar cycle. This variability has been estimated to be less than 20 per cent in the 170-210 nm region and less than 2 per cent in the 210-300 nm region⁸, and Fig. 3 shows that a decisive improvement of accuracy is needed if the Sun's UV variability is to be determined.

Solar flares

Although it is known that there are highenergy electrons in the Sun's atmosphere during solar flares, fundamental questions remain about the nature and location of the

Fig. 3 Recent measurements of solar UV irradiance in the spectral region between 170 and 200 nm (after ref. 6).

mechanisms by which the electrons are energized and their energy dissipated. It is, however, believed that a flux of magnetic energy from the solar interior provides the energy for these events, and that interactions of the accelerated particles with the Sun's atmosphere dissipate this energy, leading to observable flare phenomena including X-ray emission. Similar bursts of energy observed by the Einstein Observatory from other stellar objects have established that flares are relatively common. Hard X rays emitted during flares carry unique information about the motion of the electrons producing the radiation9. A definitive observation of the state of polarization of the radiation could provide important data to test theoretical models of the flare phenomenon.

The Solar Flare X-ray Polarimeter on OSS-1 aims to observe flare X rays emitted between 5 and 30 keV and to measure their polarization as a function of time and photon energy. The instrument uses blocks of metallic lithium surrounded by xenonfilled proportional counters as detectors. If polarized, the incident X rays will be scattered preferentially by the lithium into directions normal to the plane of the electric vector of the incoming radiation. To avoid instrumental effects that have plagued previous measurements, the instrument uses three independent sets of scattering blocks and detectors, with each unit rotated by 120° with respect to the other two about a line passing through the Sun. A minimum of two units is necessary to determine the magnitude and orientation of polarization; the use of a third provides redundancy and increased effective area10.

The instrument will be aimed at the Sun by orienting the entire bay of the Orbiter and it is planned to maintain the Orbiter in this orientation for approximately 28 hours. Solar flares occur only sporadically on the Sun, so that the observation of flare emission is not assured. However, the instrument has sufficient sensitivity that even a small event can yield a usable signal. Such events can be expected to occur about once a day on average.

Zodiacal light

The zodiacal light arises from sunlight scattered or absorbed by interplanetary dust particles, the characteristics of which have been partly defined by rockets and unmanned Earth-orbiting satellites11. Observations of colour, polarization and angular dependence are needed to determine dust particle size and composition¹². Unfortunately, accurate data are scarce. Thus, polarization results at different wavelengths are often combined. There are some observations of brightness, but few of polarization and colour in regions off the ecliptic, closer than 30° to the Sun and near the anti-solar point — the regions which contain the most information on the dust. The Shuttle Spacelab Induced Atmosphere Experiment

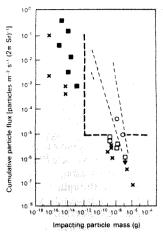

Fig. 4 Measurements of near-Earth microparticle fluxes by various techniques: , impact plasma sensors; ×, capacitor discharge sensors; O recovered surface examination; , perforation of pressurized cylinders; dashed lines, models derived from microphone sensors. The area to the upper right of the heavy dashed line is the sampling regime of the Microabrasion Foil Experiment on OSS-1. The cumulative particle flux is the flux of particles above a specific mass. Adapted from ref. 14.

will provide observations to determine more precisely the position of maximum concentration of interplanetary dust and will search for evidence of different particle characteristics for dust near the Sun.

Although astronomical observations from space avoid the effects of the Earth's atmosphere, the observing platform releases particulates which may form a local contaminant cloud that will also scatter sunlight into the detector. The presence of such an induced atmosphere can be established by comparing observations made when the spacecraft is in sunlight and in the Earth's shadow. The photopolarimeter system on OSS-1 will measure the light scattered from any local cloud of particulates and will record the brightness, polarization, colour and angular dependence of the diffuse astronomical background (zodiacal light and background starlight) at visual and near IR wavelengths.

The instrumentation to be used is the spare unit of the Skylab S073 photopolarimeter and bore-sighted 16 mm camera. The system, which includes an optical train, optical filters for 10 wavelength bands between 400 and 820 nm, a polarization analyser, a brightness calibration source and a photoelectric sensor, can carry out observing sequences according to pre-programmed routines. Although the instrument was operated on Skylab, difficulties with the airlock precluded observations closer than 80° to the Sun. A new gimbal mount has been designed for this mission, allowing the instruments to be scanned in a vertical plane running fore and aft along the Orbiter axis. The instrument will view the entire sky between 20° and 120° from the Sun. Limited observations will also be possible at larger angles.

Interplanetary dust

Direct sampling of interplanetary particulate matter has been carried out from balloons, U-2 airplanes, rockets, Earth-orbiting spacecraft13. Remote measurements have been made with sensors in Earth orbit and interplanetary space14. Even impact craters in lunar samples have provided valuable information. A wide range of particle masses, down to 10-15g have been observed, with the cumulative particle flux increasing strongly with decreasing mass (Fig. 4). While comets are thought to be the most likely source of interplanetary dust, direct measurement of particle composition could discriminate between cometary and asteroidal sources for the dust.

The Microabrasion Foil Experiment aims to measure the high velocity microparticle flux in near-Earth orbit, for particle masses greater than 10⁻¹²g, to investigate the density distributions of the impacting particles and to study their chemical properties by analysis of residues remaining in the impact craters. The sensor, attached to the thermal blanket on top of the thermal canister experiment, consists of approximately 1 m² of 5µm thick aluminium foil bonded to a gold-coated brass support mesh bonded to a Kapton sheet to form a double layer detector.

Differing types of impacts may be recorded. A particle of mass < 10⁻¹²g will form a hypervelocity impact crater on the foil surface, without penetrating the foil. More massive particles will penetrate the foil forming a characteristic 'penetration profile', dependent on the particle's incident velocity. Particles penetrating the foil may survive intact to produce a single impact crater on the rear Kapton sheet, or the particle may split into fragments and produce a corresponding number of impact craters on the sheet. Low density "fluffy" particles readily fragment

whereas high density iron or stony micrometeorites survive almost intact.

Unlike the other experiments, the Microabrasion Foil Experiment is passive. Post-flight measurements of the craters with scanning electron microscopy and energy dispersive X-ray microprobe analysis of residues will provide information on elemental composition, density and shape, and thus on the origin of these particles.

Plant lignification

Although few plants have been grown in space, Russian experiments have demonstrated that near-zero gravity disorients root and shoot growth, enhances plant sensitivity to substrate moisture conditions and generally results in a high mortality rate. However, little is known about the physiological changes that occur. Understanding of gravity's effects on plant growth and metabolism will provide an insight into plant physiology and aid development of an effective biological life support system.

After cellulose, lignin is the most abundant carbon compound in plants and provides both their strength and form. As gravity is believed to be a primary controlling stimulus for lignification the Plant Lignification Experiment will evaluate how near zero gravity affects the quantity and rate of lignin formation in different plant species during early stages of development.

Of the major groups of higher plants the gymnosperms will be represented by slash pine, the monocotyledonous angiosperm by oat, and the dicotyledonous angiosperm by the mung bean. All are compact species that may be grown in the limited space and relatively low light levels provided by the compact flight Plant Growth Unit. Oat and mung bean seeds and young pine seedlings will be planted in the growth chambers (Fig

5) before launch so that most seedling development will take place in a weightless environment. Electronics for controlling and monitoring temperature and light cycles are incorporated into the Plant Growth Unit. At the latest convenient time (about 7 hours before launch) the unit will be carried on board and installed in a middeck locker of the Orbiter cabin, where it will remain throughout the flight.

On landing, the Plant Growth Unit will immediately be removed from the Shuttle, the plants photographed, and the gaseous atmosphere of the plant chambers analysed. The seedlings will then be removed and analysed for lignin content.

Control experiments, with the plants growing in a 1-g environment, will be conducted after the flight using the flight hardware and flight environmental data. Lignin data from the flight and control plants will be compared for patterns of lignin deposition to assess whether lignin is reduced in plants grown in zero gravity.

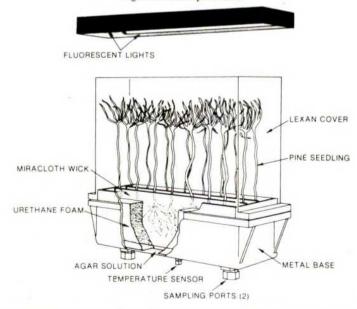

Because the reduced flight time of the previous Orbiter flight prevented completion of the Heflex (plant) Bioengineering Test that it carried, this experiment has been added to the current flight and is also carried in the Orbiter cabin. The test is being conducted specifically to determine the optimal soil moisture conditions for germination and growth of the sunflower *Helianthus annus* in near zero gravity. It is a prelude to a plant growth experiment to be conducted on the first Spacelab mission to be flown on the Shuttle in 1983.

Thermal canister

The long-term use of Space Shuttle means that many scientific and technical investigations can be performed in the Orbiter bay. However, the extreme thermal environmental conditions ranging from equivalent sink temperatures of + 100°C in full Sun, to -100°C, in shadow may cause problems. In the past such conditions were accommodated using coatings, insulation and heaters. With the Shuttle, an instrument designed for one set of conditions may have to survive in an entirely different environment if flown again with different orbit attitudes. If a thermal enclosure were provided which decoupled instruments from the wide extremes in external tempeature whilst maintaining them in a benign environment, simpler thermal designs for instruments, with limited maintenance between flights, might be realized.

To this end the Thermal Canister Experiment aims to determine whether a device using controllable heat pipes could maintain simulated instruments at several selectable temperature levels in zero gravity, and under widely varying internal and external thermal loads. It is hoped to demonstrate ±3°C temperature stability at various control points in the canister while dissipating up to 400 W in cold Orbiter attitudes (bay away from the Sun)

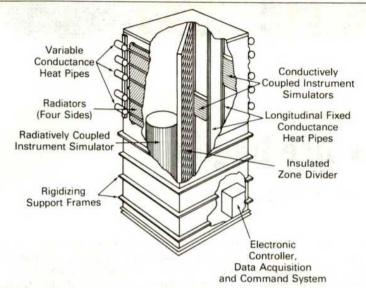

Fig. 6 Cutaway view of the Thermal Canister Experiment showing controllable heat pipes. In flight conditions, the lower half of the unit is covered with multi-layer insulation to provide a measure of isolation from temperature extremes in the Orbiter bay.

and 100 W hot (bay towards the Sun) conditions.

The Thermal Canister Experiment (Fig. 6) consists of a rectangular enclosure 3m high × 1m long × 1m wide with its aluminum sides equalized in temperature by a system of longitudinal fixed conductance heat pipes. These heat pipes collect the thermal energy dissipated internally by electrical heaters simulating instruments in operation and the energy absorbed from direct and reflected sunlight. This heat is then conducted to variable conductance heat pipes mounted to external radiators at the upper end of the canister and radiated to space. The heat pipes are long narrow closed chambers with internal capillary wicking which provides pumping action. The wick is saturated with a volatile liquid (ammonia) in equilibrium with its vapour. Heat transport is established by applying heat at one end (the evaporator) and providing cooling at the other end (the condenser) with the heat being trasferred as latent heat of vaporization. The flow path is completed by capillary forces in the wick.

The variable conductance heat pipes are more complex than the fixed conductance type in that they contain a non-condensible gas (nitrogen) stored in a reservoir at the condenser end of each pipe. As the temperature of the evaporator end of the pipe falls a heating element raises the temperature of the reservoir, causing the gas to expand into the condenser, blocking the condenser region and effectively stopping heat pipe action. The length of condenser rendered inactive depends on the temperature level along the pipe. Conversely, with increasing evaporatorend temperature, the gas will recede into the reservoir making more active area of the radiators available for heat rejection to space. The signal for activating the reservoir heaters is supplied through a feedback loop consisting of a temperature control sensor and either a hardwire proportional controller or a computerdriven controller. The sensors are attached to the canister side walls or on simulated instruments located in two different zones separated by an insulating barrier. The simulators are either radiatively or conductively coupled to the canister walls.

During the mission, it is planned to: (1) operate the canister over set points (5-25°C) located on the walls and on the simulators themselves; (2) change the internal dissipation (in the simulators); and (3) demonstrate control in maintaining the two zones at differing temperatures. The system can be operated by a proportional controller maintaining a specific temperature at one sensor, or by a microprocessor that uses all available data to maintain the overall temperature of the canister at some level, in balance with the environment, irrespective of the preselected set point.

Contamination monitoring

Payloads operating in the bay of the Orbiter will be exposed to a variable gaseous environment. In addition to outgassing of the vehicle and the payloads themselves, the operation of altitude control systems, the venting of relief valves and the dumping of water for thermal control of the vehicle all represent molecular sources that may affect sensitive instrumentation, particularly equipment at cryogenic temperatures. Measurements have been planned for the series of four orbital test flights using the Induced **Environment Contamination Monitor** provided by the Marshall Space Flight Center and located, on this flight, behind the OSS-1 pallet in the Orbiter bay. Particulate measurements will be provided by the Shuttle/Spacelab Induced Atmosphere Experiment. A molecular contamination monitor on the OSS-1 pallet provides information on molecular species around the OSS-1 instruments, supplementing measurements from the Induced Environment Contamination Monitor.

The Contamination Monitor Package, sponsored by the United States Air Force, contains four temperature-controlled Quartz Crystal Microbalances which measure the accreted mass of molecular fluxes. These microbalances are identical to those contained in the Induced **Environment Contamination Monitor but** their operation can be monitored and the data analysed during the flight. Their temperatures may be reset by command after initial results have been analysed to optimize the operation of the sensors.

The instrument will monitor the mass accretion of condensible volatile materials during ascent, on-orbit operations and descent. After the mission, the data on mass build-up will be correlated with payload activities, Orbiter operational events, performance of other OSS-1 instruments and Induced Environment Contamination Monitor results. The activation energy of the major species of the accreted materials can also be estimated.

While minimal impact is expected for most instruments that may fly on Shuttle, long-term exposures of particularly sensitive optical components or cryogenic surfaces to the Orbiter environment may require special precautions.

Future prospects

The OSS-1 instruments will point the way to future developments in the use of the Shuttle for space science investigations. Two of the OSS-1 instruments will fly again on the Spacelab-2 mission: the Plasma Diagnostics Package will be released from the Remote Manipulator System to become a subsatellite and make measurements of the spacecraft wake at distances up to 20 km behind the Orbiter, while the Solar Ultraviolet Irradiance Monitor will be mounted on a solar pointer to continue UV irradiance measurements through the solar cycle. The data from other experiments will be used to design large UV and IR telescopes and other instruments for future flights in the Orbiter. Ultimately, the Shuttle program will include disciplinededicated flights and the development of space platforms serviced by the Shuttle.

NEWS AND VIEWS

How life began

from Preston Cloud

THE prebiotic Earth, the beginnings of life and the evolution of biological complexity were the subjects of a small symposium* of 27 participants from Australia, Canada, the Peoples' Republic of China and the United States held recently at Jindabyne, New South Wales.

The now-large group of polyatomic organic molecules known from galactic space as a result of radioastronomy linked with spectroscopy extends the plausible choices available for the initial building blocks of life. Brown (Monash University) described contributions from (1) chemical evolution in the dark nebulae of the Galaxy; (2) chemical evolution in the presolar nebula followed by the arrival on Earth of its products in planetesimal debris; and (3) chemical evolution in Earth's primitive atmosphere and hydrosphere. The arrival in the early solar nebula of cold organic molecules from the interstellar stockpile appealed to Chang (NASA); had they been warmed on entry, ices would have melted, and a lot of aqueous chemical evolution might have occurred in restricted environments.

The heavily cratered surfaces of the solid planets and satellites were cited by Taylor (ANU) as evidence that planetesimal infall continued until about 3.8 Gyr (3.8×10^9 yr) ago, wiping out earlier records of earth history. Meanwhile Earth's core and mantle had formed, a conclusion drawn by Sun (CSIRO) from the constancy from 3.8 Gyr ago until the present of the ratio of P_2O_5 to TiO_2 in mantle-derived basalts. The motions of a fluid core can generate the magnetosphere that shields Earth's surface from the potentially lethal solar wind.

With a source of prebiotic organic molecules and such shielding, chemical evolution along the continuum from nonliving to living could occur at sites shielded from lethal UV wavelengths. The central problems of biopoesis (N.W. Pirie's word for the origin of life) are how to achieve the necessary concentrations of organic macromolecules, how to catalyse the essential reactions and how to accomplish chirality.

The chemistry of the atmosphere under

*The symposium was held from 13 to 15 December 1981 under the joint sponsorship of the Australian Academy of Science and the National Academy of Sciences of the USA.

which life arose is important. Earlier views invoking highly reducing conditions are giving way to geochemical evidence for a nearly neutral atmosphere. Fluid inclusions in 3.5 Gyr old barite show CO₂, H₂O, H₂S and possible hydrocarbons (Groves, UWA). An atmosphere at this time of CO₂, H₂O, N₂ and CO, with minor proportions of NH₃, H, CH₄ and H₂S, seems likely. Experiments on chemical evolution show small but finite yields of interesting organic molecules under such an atmosphere in the absence of free O₂. Carbonaceous chondrites might even more successfully concentrate amino acids and nucleotide bases in wet clay banks that could promote dehydration condensations. And the chemistry of Archaean sediments argues for very low and evanescent free O2. In fact, the real problem with oxygen is not to account for its absence in earlier times but for its presence later. Because the co-products of the processes that produce it are all thermodynamically unstable, free O₅ can accumulate only as the product of a kinetic

Sedimentary rocks 3.8 Gyr old are evidence for a substantial atmosphere and hydrosphere in earliest Archaean time. Despite the faint early sun of solar physicists, liquid H₂O has been present at Earth's surface from then onwards. McCulloch (ANU) described these oldest known sediments as implying derivation from undifferentiated source rocks—hence from crust formed no more than 200–300 million years earlier, about 4–4.1 aeons ago.

Returning to the question of biopoesis, the origin of replication was the subject of spirited discussion. Reanney (La Trobe University) proposed that RNA came first, as implied by the appearance of ribose before deoxyribose in existing biosynthetic pathways. But Langridge (CSIRO) reasoned that DNA came first because its bonds resist hydrolysis more strongly than those of RNA. Or did something else start the process? Burgess (Ludwig Institute) proposed that sugars were the logical beginners because they form readily, have a limited rotational freedom, will form helices with catalytic properties, are stable and link with lipids to form micelles.

But, in prebiotic evolution, how are sequences replicated and copying errors limited? Replication would be favoured, Reanney supposed, by day-to-night temperature variations. Experimentally, strands of DNA separate on heating and recombine when cooled. Such a mechanism could be important on an early Earth with shorter days and hence more rapidly repeated cycles.

Chirality may not be as much of a problem as once supposed. Brown remarked that once as many as five amino acids of the same handedness are strung together, they will preferentially add other amino acids of similar handedness from racemic mixes. To get five amino acids or sugars of the same handedness lined up by chance is entirely probable. And given a metabolizing, self-replicating structure, mutation is the next essential property. Copying error prescribes mutation and mutation predisposes to evolution.

Anderson (CSIRO) then showed how colloidal systems, bilayer vesicles and, ultimately, cells could result from the propensity for self-organization of amphipathic lipids and proteins. The distinctive properties of membranes permit the energy transduction that results in living cells.

Much attention at the symposion was directed to the earliest known forms of life and to their probable biochemical evolution. Evolution beyond fermentation requires photosynthesis and phosphorylation to trap and maintain a freeenergy flow. By what routes, Anderson (CSIRO) asked, could photosynthesis and respiration arise? Mauzerall (Rockefeller University) sees biosynthetic pathways as recapitulating evolution. Each porphyrin on the path to chlorophyll biosynthesis had a specific function in its own time. The first porphyrins of the haem/chlorophyll biosynthetic pathway, the uroporphyrins, were presumably the initial photo-oxidants that later became coupled to phosphorylation and photosynthesis. Bacteriorhodopsin, present in halophilic bacteria, is the most primitive surviving

Preston Cloud is at the Baas-Becking Geobiological Laboratory, Box 378, Canberra City, ACT, Australia. molecular device to promote ion flow across membranes.

Walter (Baas Becking Laboratory) reviewed the fossil evidence and Hayes the biogeochemical evidence for early evolution. They concluded that life was present by 3.5 and photosynthesis by 2.8 Gyr ago in the Warrawoona and Fortescue strata of Western Australia.

An extended discussion followed about the importance of sulphur in living systems, the geological record of sedimentary sulphate and S isotopes, the possible importance of methanogens and the question of when free O, from photosynthesis first became an important atmospheric gas. Groves noted that sulphates are uncommon in Archaean rocks whereas sulphides are abundant. Donnelly added that the sulphur isotope record of stratabound volcanogenic sulphide deposits calls for very low concentrations of oxidized sulphur in the Archaean hydrosphere. The record observed is consistent with the convergence of three important and perhaps related events ~ 2 Gyr ago: (1) the beginning of free O₂ as a permanent component of the atmosphere, (2) the end of methanogenesis as an important function of the biomass, and (3) the onset of dissimilatory sulphate reduction.

The emergence of the eukaryotic cell at some time after ~ 2 Gyr ago was the focus of the final session at Jindabyne. Walter reviewed the biogeological evidence for the rise of O, during Earth history, the probable time of emergence of the eukaryotes and alternative hypotheses for eukaryotic origins. Runnegar (New England University) observed that even anaerobic eukaryotes need O2 for the production of collagen and components of the cell wall. Thus eukaryotes probably made their first appearance later than 2 Gyr ago. But how? Langridge observed that differences between organellar and nuclear DNA of eukaryotes could result either by derivation of the organellar DNA from the nucleus by a transfer analogous to that involved in the origin of some viruses, or by endosymbiosis.

Lastly the conference turned to the origin of membrane-bound organelles, considered distinctive of the eukaryotic cell. Langridge noted that cytochrome c amino acid sequences and 5S rRNA nucleotide sequences imply a date of ~ 1.8 Gyr ago for the divergence of the eukaryotic from the prokaryotic level of organization - a date consistent with biogeological evidence. No serious alternative was offered to serial endosymbiosis for the origin of the eukaryotic complement of membranebound organelles. Discussion concentrated instead on which of these organelles might have come first. Starting with a nucleated host, most preferred first to add mitochondria of probable bacterial origin and then chloroplasts, whose 16S rRNA sequences imply a blue-green algal origin.

Was Galileo 2,000 years too late?

from David W. Hughes

SIDEREUS NUNCIUS was published in Venice in 1610 and revealed to the renaissance world "great, unusual, and remarkable spectacles as observed by Galileo Galilei, Gentleman of Florence, Professor of Mathematics in the University of Padua, with the aid of a spyglass". The title page also announced that the greatest discovery was that of the "four planets swiftly revolving about Jupiter at differing distances and periods, and known to noone before the Author recently perceived them and decided that they should be named The Medician Stars". One of Galileo's notebooks records how Jupiter was seen on 7 January 1610 with three companion 'fixed stars', two to the east and one to the west. Galileo concluded, after a week of observation, that "there are three wandering stars around Jupiter, previously invisible to everyone".

Galileo's claim to priority has recently been shown to be unjustified; and it is not a matter of being just pipped at the post, but of some 2,000 years.

Xi Ze-zong, of the Institute for the History of Natural Sciences, Academia Sinica, has recently reported in *Chinese Astronomy and Astrophysics* (5, 242; 1981) that Gan De observed Ganymede in the summer of 365 BC.

Gan De was one of the earliest Chinese astronomers and was an assiduous observer of the heavens, and in particular of the planet Jupiter. He wrote two books, Treatise on Jupiter and Astrological Prognostications. Both have been lost but fortunately portions have been preserved in The Kaiyuan Treatise on Astrology which was compiled by Qutan Xida between AD 718 and 726. Gan De is quoted as having said:

"In the year of chan yan . . ., Jupiter was in Zi, it rose in the morning and went under in the evening together with the lunar mansions Xunü, Xü and Wei. It was very large and bright. Apparently, there was a small reddish star appended to its side. This is called 'an alliance'."

The reference to the zodiacal division Zi and the lunar mansions reveals that the observation was made in the summer of 365 BC and the use of the term 'in alliance' that the small star is described as a subsidiary of Jupiter. The colour 'chi' is a light red.

Xi Ze-zong puts forward no explanation as to why this reference to a satellite of Jupiter has been overlooked until now.

Which satellite was it? Jupiter has four 'galilean' satellites, Io, Europa, Ganymede and Callisto, and when Jupiter is in opposition, at its closest to Earth, these have magnitudes of 4.9, 5.3, 4.6 and 5.6 respectively (a change of 1.0 in magnitude is equivalent to a factor of 2.5 in brightness and bright objects have low magnitude values). At opposition the maximum

angular separations between the satellites and Jupiter are 2.3, 3.7, 5.9 and 10.1 arc min respectively. Ganymede is thus the brightest moon and can be as much as 5.9 arc min away from Jupiter — one-sixth the apparent diameter of the Moon. Unfortunately, Jupiter then has a magnitude of around -2.6 and is thus 760 times brighter.

Xi Ze-zong used a planetarium to simulate two sources differing in brightness by a factor of 760 and separated by 5.9 arc min. People with good eyesight could detect the fainter object. Xi Ze-zong could, however, have saved himself some trouble by turning to a more recent 'ancient tome'. Admiral William H. Smyth wrote in his Celestial Cycle, Vol. 1 (1844) that

"Certain esprits fort express surpise that Galileo should have been so gratified by this discovery since they hold that the satellites of Jupiter are often seen with the naked eye and they cite the Apennines and Etna and the West Indies and various other fine-climate places as the spots where such a feat is frequently done."

Smyth concluded, however, that the observer must not only be at a site of fine seeing and excellent atmospheric clarity but must also possess "visual organs of extraordinary power".

Two problems still exist. We cannot be sure whether Gan De saw Ganymede or Callisto. Ganymede is the more probable simply because it is the brighter. The reference to the 'light red' colour is also mystifying. Ganymede is too faint for its colour to be perceived with the naked eye. Even in a telescope it appears white and has a very similar colour to that of Jupiter.

This the hundredth article written written for News and Views by David W. Hughes, a lecturer in physics and astronomy at the University of Sheffield. The first, 'Meteors and Meteorology', was published on 13 June 1970 (Nature 226, 1008).

Molecular recognition and the future of monoclonal antibodies

from David Lane and Hilary Koprowski

A MOST striking revelation to emerge from recent experiments with monoclonal antibodies has been the repeated demonstration of cross-reacting sites on molecules in which conventional serology had failed to detect homology. The most obviously suggestive of these crossreactions are those which have been found between the large T antigen of simian virus 40 (SV40) and normal proteins of host cells1,2. At least four monoclonal antibodies against the T antigen, which is strongly implicated in the oncogenicity of the virus, can be shown to cross-react very specifically with host proteins, one of which, a ubiquitous protein of molecular weight 68,000, is regulated by cell growth.

Other cross-reactions, all equally specific but not all as obviously suggestive, have been detected between various other more or less related molecules. The well characterized rat monoclonal antibody 42-21, for example, binds both Thy-1 antigen and the Vx chain of immunoglobulin molecules bearing the TEPC-15 idiotypic determinant3. A monoclonal antibody obtained after immunization of mice with herpes virus4 binds a glycoprotein specific to the virus and virus-infected cells, but also crossreacts with neutral glycolipids extracted from normal uninfected cells⁵. Yet other monoclonal antibodies cross-react with two cytoskeletal proteins, tropomyosin and vimentin6; and another cross-reacts with Thy-1 antigen and intermediate filaments⁷. Probably yet more apparently capricious cross-reactions have been detected but not reported.

What do they mean? The most exciting possibility is that these antibodies are detecting the conserved recognition sites underlying the specific macromolecular interactions that control most important biological processes. But there are serious difficulties in using monoclonal antibodies as the sole indicator of molecular identity. These difficulties are well known to immunochemists, but they may not be fully appreciated by the growing numbers of workers new to the field of immunochemistry who are now turning increasingly to monoclonal reagents in preference to conventional antisera. Before expanding on the potential of monoclonal antibodies in the exploration of molecular recognition, therefore, we shall reconsider the character of polyclonal antisera and the nature of antibody specificity, and discuss how these bear on

David Lane is in the Eukaryotic Molecular Genetics Research Group, Department of Biochemistry, Imperial College of Science and Technology, London SW7 2AZ, and Hilary Korowski is at the Wistar Institute, 36th and Spruce Street, Philadelphia, Pennsylvania 19104.

the interpretation of immunological crossreactions between molecules.

There are two crucial points to be considered, the first of which is the heterogeneity of conventional polyclonal antisera. A conventional antiserum raised in a rabbit against bovine serum albumin, for example, contains a large number of different antibodies directed against different discrete determinants or epitopes on the surface of the bovine albumin molecule. Some of these epitopes will also be present on a related molecule such as human serum albumin, and the two antigens will thus be cross-reactive. Other epitopes, on the other hand, will be present only on one or other albumin molecule. By

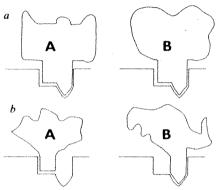

Fig. 1 Two ways a monoclonal antibody could cross-react. a, Protein antigens A and B have the same shape over part of their surface. b, A and B have different structures but interact with the same antibody molecular.

appropriate absorption experiments polyclonal antisera can be used to distinguish the cross-reactive and the noncross-reactive epitopes and are thus powerful tools for such purposes as determining phylogenetic relationships between species⁸. Evidently a single monoclonal antibody will never yield this kind of information; and so complex are conventional antibody responses that it would be extremely difficult to mimic them with artificial 'cocktails' of monoclonal antibodies.

But the ease with which homologies between proteins can be detected by conventional antisera depends not only on the intrinsic structure of the antigens but also on the host response to them, which can result in important blind spots in individual sera. For the antibodies produced in a normal immune response are not evenly directed against all parts of the surface structure of the antigen. Rather, most antigens have clearly immunodominant regions which in some cases, for example the influenza haemagglutinin, have been closely mapped⁹. The relative immunodominance of given regions on a protein molecule may

vary between different host animals. For example, different strains of inbred mouse preferentially make antibodies to different areas of the staphylococcal nuclease antigen¹⁰; and certain mutant determinants on human haemoglobin molecules cannot be recognized by rabbit antisera because they cross-react with rabbit haemoglobin, to which the animal is immunologically tolerant¹¹. Such factors will restrict both the ability of individual conventional sera to detect cross-reactions between antigens and, of necessity, the range of monoclonal antibody specificities that can be obtained from a particular cell fusion.

The second important consideration in the interpretation of cross-reactions is directly relevant to the use of monoclonal antibodies, and concerns the nature of the antibody response to a single epitope and the interactions between one pure clonal antibody and that structure. In a conventional antiserum, not only are numerous different antibodies directed against different determinants on the same molecule, but a very large number of different antibodies will react with each single epitope, recognizing it with different degrees of affinity. This extraordinarily diverse response to a single epitope, which may be a very simple artificial determinant such as dinitrophenol, has attracted detailed examination because of its implications for the genetic basis of antibody diversity. A theoretical consideration of the problem led Talmage¹² to propose that one antibody binding site might be polyfunctional and accommodate more than one epitope. He then reasoned that some antibodies would be produced in the immune response to several different antigens and the full range of specificities might be achieved by fewer different antibodies than might at first seem necessary. Thus epitope A would stimulate clones of antibodies with specificity for epitopes A, B, C, D; A, E, F, G; A, H, I, J, and so on. The serum would then bind predominantly epitope A, present on the eliciting antigen. The important implication for monoclonal antibodies is that one would not expect them to show the same degree of A-dominance as the polyclonal serum: they might react equally well with another epitope, for example B, that the whole serum recognizes at such a low titre compared with A as to render it undetectable. This important hypothesis was examined in detail by Richards and colleagues13 who obtained direct experimental proof for the existence of polyfunctional binding sites; thus, a myeloma protein (460) was found to bind two structurally unrelated molecules dinitrophenol-lysine and 2-methyl-1, 4-naphthoquinone (menadione) at sites that could be shown to be physically

Bounded brainpower? from Paul Davies

Is there a limit, due to fundamental physics, on the rate at which information can be processed in a computer? "Yes" claims Jacob Bekenstein, the co-inventor of the quantum black hole. In a provocative paper published in *Physical Review* a year ago, he claimed that the bread and butter of information transfer—energy and entropy—cannot be varied at will, but are constrained by the bound

$$\frac{\text{entropy}}{\text{energy}} < \frac{k}{\hbar c} \times \text{size} \tag{1}$$

where $h = h/2\pi$, the size of the system is defined in some suitable all-embracing sense, and k, h and c are respectively Boltzmann's constant, Planck's constant and the velocity of light.

Bekenstein went on to assert (*Nature* **292**, 112; 1981) that this bounded ratio of entropy to energy also constrains the rate of information processing to be less than

$$\frac{\pi k}{\hbar}$$
 × energy (2)

Taking into account the need to flush out the heat produced in a hypothetical computer by the information's energy, Bekenstein estimated the upper limit to be about 10¹⁵ bits per second (still pretty fast).

Now all this has been called into question by David Deutsch of Oxford University's Department of Astrophysics. In *Physical Review Letters* (48, 287; 1982), Deutsch challenges the fundamental basis of Bekenstein's analysis — the existence of an entropy to energy bound [equation (1)]. Energy, he points out, is not itself a measurable quantity in non-gravitational physics. Only energy differences are relevant to devices such as computers. Bekenstein's formula (1) might work for systems such as black holes, where gravity plays a part, but it has no business to interfere where

gravity is unimportant. (Energy, having mass, is a source of gravity, so its absolute value can be measured gravitationally.)

Deutsch reworks Bekenstein's calculation for energy differences and finds that there is no upper bound on the entropy to energy difference ratio. He then argues that it is this ratio that is relevant to information processing. The essential point is that not all the energy carried by the information generates heat in the computer, only the energy change due to the encoding procedure. The rest is invisible to everything except the gravitational field. He also throws in, for good measure, the retort that, in any case, it is in principle possible, even in quantum physics, to retrieve information by measurements that leave the information undisturbed, and hence do not produce heat.

So the current state of play is that Bekenstein's bound (1), while not incorporating the newtonian gravitational constant G explicitly, is nevertheless a gravity formula in disguise, to be used only when the system concerned runs on gravity power. In that case, if a computer is too big, its thinking time is limited by the speed of light; too small and it implodes into its own black hole. In this sense, bound (1) may provide a genuine limit, which Deutsch estimates at around 10^{42} bits per second!

Alas, even the gravitational applications of equation (1) have recently been called into question by William Unruh, Robert Wald, Don Page and Stephen Unwin in some lively exchanges (*Physical Review* D, in the press). Evidently the embattled Bekenstein has caught the attention of more than the computer industry.

Paul Davies is Professor in the Department of Theoretical Physics, University of Newcastle upon Tyne, Newcastle upon Tyne NEI 7RU.

discrete (though the two haptens did compete for the binding site).

In light of these considerations, there are two distinct explanations of the physical basis of monoclonal cross-reactions. One interpretation is illustrated in Fig. 1a, where protein antigens A and B share a small and precise detail of their surface topology. Such a determinant might not normally be detected using conventional antisera in which most of the antibodies will be directed against other A-specific or B-specific structures; only dissection of the antibody response using the monoclonal technique reveals the shared structure. The question then becomes one of just how significant such small homologies are.

In the second explanation (Fig. 1b), the two protein antigens have dissimilar structures but interact with the same antibody molecule. It is notable that the

two different antigens could still compete for binding to the antibody because of steric constraints, even though their reactive epitopes, by analogy with the myeloma 460 example, occupy discrete sites on the molecule. However, the affinity of the antibody for antigens A and B would then be expected to be much lower than in the alternative model illustrated in Fig. 1a. In the second model (Fig. 1b) there is no reason to assume any biological relationship between the cross-reacting antigens; the only factor of interest in the system is the existence of the cross-reactive antibody itself. The production of such antibodies, for instance, could contribute to an autoimmune response induced by a structurally completely unrelated antigen. These two models represent the extreme alternatives and of course it must also be possible for the epitope on antigen A to be

only partly homologous to the epitope on antigen B, so that the antibody binds antigen A with higher affinity. Detection of such cross-reactions, whatever their molecular basis, means that reaction with a monoclonal antibody cannot itself be interpreted as proving molecular identity. For example, the reaction of a monoclonal antibody with two different cell types still requires biochemical verification that an identical molecule is being recognized in each cell. Similarly, such reactions might constrain the use of monoclonal antibodies in radioimmunoassay. Clearly, both of the extreme models have some validity, and examples of both types of cross-reaction will be discovered. Our bias is that the physical basis of the majority of crossreactions detected so far is nearer to that illustrated in Fig. 1a, because they seem so highly specific. For example, the Pillemer and Weissman antibody shows no detectable binding to Thy-1-negative mutant lymphoma cells or to any IgG except that of the T-15 idiotype, and one of the SV40 T monoclonals has a very high affinity for T yet uniquely recognizes a single low-abundance 68,000 host protein on Western blots of total proliferating cell homogenates. (It does not recognize any protein at all when the extracts are made from the same cells in a quiesent state.)

The question then becomes one of just how functionally significant these small homologies between proteins are. That some are significant is nicely illustrated by the sweet-tasting proteins thaumatin and monellin. Hough and Edwardson14 have shown that polyclonal antibodies against thaumatin mimic the sweetness receptor, in that other sweet-tasting substances displace 125 I-labelled thaumatin from the antibody with an efficiency that correlates well with their relative sweetness. Of particular interest is the very effective competition between thaumatin and another very sweet-tasting plant protein, monellin, because the primary sequences of these two proteins show surprisingly little homology. Thaumatin has a single chain of 207 amino acids, and monellin has two chains totalling 94 amino acids; the homology is limited to five identical tripeptides15. We can infer that the antibody response has been selective for the biologically active region of the molecule, and by concentrating itself in a biologically relevant structure has mimicked a receptor.

A similar example of receptor mimicry by antibodies can be seen in the studies of Sege and Peterson¹⁶ where anti-idiotypic antibodies, raised against antibodies to insulin, were found to possess insulin-like activity themselves in biological tests. Cross-reactive monoclonal antibodies may therefore lead us to discover biologically important relationships between proteins and other macromolecules that could not have been detected by other means. After all, biological macromolecular interactions are all about three-dimensional shape

recognition, which is what antibodies do.

The virus-host interface is an especially interesting area in which one might expect to find such homologies. In the case of the oncogenic RNA viruses, Blair et al. 17 have shown the existence in normal mouse DNA of a cellular homologue to Moloney murine sarcoma virus and have demonstrated transformation of murine cells by recombination of the cloned homologous sequences and plasmids containing proviral long terminal repeat sequences of Moloney sarcoma virus. Derivation of src sequences of two murine sarcoma viruses, Harvey and Kirsten, from normal genes (sarc) of different vertebrate species such as rat, chicken, human and mouse has also been described recently¹⁸. These sequence homologies between retroviral onc genes and cellular genes have not been detected in analogous experiments using the transforming genes of the DNA tumour viruses. Structural homologies between these viruses transforming gene products and host proteins must exist19, however, and they may now be detected by monoclonal antibodies.

It is our hope that many exciting new correlations between important macromolecules not readily detectable by other means will emerge from these studies and increase our understanding of biological organization.

Genetic diagnosis of the fetus

from Stuart H. Orkin

THE past decade has seen rapid progress in the development of reliable methods for the identification of genetic disorders in the human fetus. Chromosome abnormalities, such as Down's syndrome, are now routinely detected during mid-trimester by the analysis of fetal cells shed into the amniotic fluid. Structural abnormalities. such as neural tube defects, may be due to many factors but can now often be detected by screening for α -fetoprotein in maternal blood and amniotic fluid. Enzyme deficiencies related to single gene disorders may also be identified from the culture of fetal cells, obtained by the safe and simple aspiration of amniotic fluid in midtrimester.

Many disorders, however, are not readily detectable in fetal cells from amniotic fluid because expression of the relevant genes is restricted to particular cell types. Conditions affecting either the structure or synthesis of the polypeptide chains of haemoglobin are the best known examples. Sickle cell anaemia, the result of the most common structural abnormality of the human β -globin chain, and β -thalassaemia, the consequence of underproduction of β -globin chains, are disabling genetic disorders of widespread occurrence. Only since the mid-1970's have new methods, the most recent of them employing the techniques of molecular

Stuart H. Orkin is in the Department of Pediatrics, Harvard Medical School.

biology to analyse the genetic material itself, begun to show success in the early diagnosis of these diseases.

The search for suitable diagnostic methods first focused on acquiring fetal blood samples since the β -globin gene is expressed, although at low-levels, during mid-trimester. This approach depended not only on reliable chromatographic methods for assaying the globin products, but also on the development of relatively safe techniques for sampling fetal blood. Direct aspiration of placental veins via a fetoscope has been especially successful although blind aspiration of the placenta has been used as well, with good results1. In both cases the risk of sampling to the fetus is of the order of five per cent, considerably above that of simple amniotic fluid taps. Such a risk is certainly acceptable in families faced with a one in four chance of having a severely affected child. By virtue of the pioneering work of Nathan, Kan, Kazazian, and their colleagues, the prenatal detection of haemoglobinopathies using fetal blood is now an accepted procedure and has been used in more than 1,800 cases2. This, in conjunction with genetic screening and counselling has reduced the birth rate of β -thalassaemics in several regions. As has often been the case in work of this kind, the technical developments have brought additional benefits it is now possible to detect haemophilia and rare granulocyte dysfunction syndromes in utero, and to assess directly fetal cell

chromosomes where amniotic cell analysis may suffer from contamination with maternal cells

The advantages of determining the presence or absence of a genetic disorder by direct gene analysis, as well as the risks involved in the acquisition of fetal blood, led in 1978 to efforts to apply novel techniques of DNA analysis to prenatal diagnosis3. Some forms of thalassaemia were known from molecular hybridization experiments^{4,5} to be due to structural gene deletions. By using specific DNA probes for globin sequences that could be labelled to high specific activity^{6,7}, bacterial restriction enzymes that cleave DNA at specific nucleotide sequences8 and the simple gel method devised by Southern9 it was possible to detect such deletions in a DNA sample of 10 µg or less. This amount of DNA could be obtained from fetal cells either directly on withdrawal of amniotic fluid or after in vitro culture. However. although the ability to detect these rare deletion states was a step forwards, for both sickle cell anaemia, which is due to a substitution in codon six of an normal β -chain sequence, and β -thalassaemia, the result of many different single nucleotide substitutions either in the coding or intervening sequences of a normal β -gene¹⁰, a more specific assay was required.

A remarkable finding by Kan and Dozy presented new alternatives. They identified a DNA polymorphism (for the enzyme Hpal) in the 3'-flanking region of the β -gene that was quite often linked with the sickle β -gene itself¹¹. By examining the B-gene fragments after Hpal digestion in family members, diagnosis of sickle cell anaemia was possible in many, though unfortunately not all, families known by linkage analysis to be at risk¹². Limitation of linkage between the polymorphism and the sickle gene to about 60-70 per cent and its variation in different world populations ultimately restricts the usefulness of this approach. The finding of additional restriction polymorphisms in the β -gene cluster does, however, extend its applicability to sickle cell diagnosis 13. Similarly, β -thalassaemia may often be diagnosed now by linkage analysis. 14,15.

Nevertheless, direct detection of the primary gene mutation would be desirable as linkage analysis generally requires careful family studies with several restriction enzymes, an affected family member and often considerable amounts of precious fetal DNA. The power of restriction enzyme mapping is such that a single base change in a restriction enzyme recognition site can be readily detected. Nienhuis first noted that the restriction enzyme MnII (recognition site GAGG) would cleave the normal but not the sickle cell codon six16. However, because Mn/I cleaves β -genes DNA very frequently, experimental use of this enzyme for sickle cell detection has not been successful.

Recently, Geever et al.17 noted that a different restriction enzyme Ddel (recognition site CTNAG) would cleave normal, but not sickle, DNA at the sixth codon. Knowing the sequences of the normal β -gene and its immediate flanking region, the sizes of the restriction fragments expected from the normal and sickle cell DNAs could be predicted. Using electrophoresis of DNA fragments in acrylamide rather than the usual agarose, covalent transfer of fragments to a solid support and larger amounts of DNA (20 µg or more). Geever et al. could distinguish the B from the normal gene in total DNA. With a similar assay Chang and Kan18 showed that the approach could be applied to prenatal diagnosis. The detection of the β^{S} in these studies is an experimental tour de force given the relatively small size of the DNA fragments detected (less than 0.4 kb). In view of the technical difficulties of this approach Chang and Kan have advocated its use when the HpaI polymorphism is not informative.

Even this achievement may now be superceded - another restriction enzyme has been discovered that cleaves a subset of *DdeI* sites. While it cuts normal β -gene at codon six it does not cleave Ddel sites just upstream from the gene. The size of the DNA fragments from normal and sickle DNA should be considerably larger than those obtained using DdeI and more suitable for gene mapping. These predictions have recently been confirmed in the present author's laboratory¹⁹. The β ^S gene can now be detected directly following digestion with this new enzyme with a sensitivity comparable to detection of the HpaI polymorphism in the usual Southern gene mapping analysis. We believe that this constitutes a simple and reliable assay for the sickle mutation in DNA.

The prospects for direct detection of B-thalassaemia mutations are less favourable, however. Some β-thalassaemia mutations can be detected directly by the alteration of the β -gene map by a specific substitution, but most, at least among Mediterraneans, cannot. Linkage aĥalysis remains, however, a useful technique in these situations^{10,14,15}. Other single-gene disorders may, in principle, be identified by linkage analysis using human DNA fragments cloned from various chromosomes, thereby extending this approach to other conditions.

Families seeking prenatal detection of genetic disorders generally choose termination of pregnancy if the fetus is found to be affected with the disease for which it is at risk. The trauma for the family, both physical and psychological, is great, especially as diagnosis is not established until the latter portion of the second trimester. Earlier diagnosis would be very desirable if risks to the fetus or mother were not appreciable. Niazzi et al.20 and Kazy et al. 21 have reported trophoblast or chorion biopsy by the transcervical route at 6-12 weeks gestation. Such material provides fetal cells, that can be grown in vitro if necessary, suitable for

chromosome, enzyme and DNA analyses22. Although early study has shown no complications associated with the prodecure, more investigation will be needed before it gains wide acceptance. Nevertheless, the prospect of obtaining fetal cells in the first trimester is exciting indeed. It will obviate the "race to the wire" that sometimes prevails in midtrimester diagnoses and may ultimately alleviate considerable psychological and physical morbidity. The availability of such procedures will provide further incentive to find methods for DNA analysis, either direct or by linkage, for many genetic diseases.

Finally, we may wonder whether totally noninvasive approaches to diagnosis of disease in the fetus might not be possible. Fetal cells normally pass in small numbers into the maternal circulation. Specific enrichment of fetal cells by cell sorting, perhaps using recently developed monoclonal cell surface-specific antibodies23, may eventually allow fetal diseases to be detected in cells obtained from maternal blood. If this is likely to be useful in situations where DNA is analysed, it may be necessary to design novel gene

probes that extend the sensitivity of present gene mapping methods. At the current pace of progress in this field, we can anticipate that we will soon be surprised by as yet unforseen developments.

Trace elements and ocean chemistry

from Michael L. Bender

THE article in this issue of Nature by Elderfield and Greaves (p.214) reflects two important trends in the study of the marine chemistry of the trace metals. First, there is increasing interest in the detailed chemical behavior of trace elements in the oceans the complexing of metals with anions and organic ligands, particle adsorption and the occurrence and the implications of trace metal redox reactions. Second, we can see the trend towards application of four of the sacred instruments of hard rock geochemistry - lead, strontium and neodymium isotopes and rare earth element distributions — to problems in marine geochemistry.

The earliest successful research on marine trace metals, begun in the early 1960s, concentrated on elements whose distribution in seawater could be accurately measured by the radiochemical study of uranium and its daughter Ra²²⁶. Subsequently, the approach has been extended to include the less abundant radioisotopes of thorium, radium, protactinium, polonium and lead. In the mid-1970's, a number of laboratories began to study the transition metals manganese, iron, nickel, copper, cadmium, zinc and chromium, which are of great interest because they are both essential and toxic to organisms, and

Michael L. Bender is in the Graduate School of Oceanography University of Rhode Island Kingston, Rhode Island 02881.

because they are enriched in both hydrothermal and normal deep sea sediments. During the last few years, considerable attention has been paid to the metalloids tin, selenium and germanium, and the methylated compounds which they form. Finally, extensive effort has gone into determining the oceanic distributions of the global pollutants, lead and mercury.

Such studies have given us a broad understanding of marine trace element geochemistry. A number of elements, including thorium, protactinium, polonium, lead, iron and manganese, are highly reactive and are scavenged from seawater into sediments within a few decades. Others, including copper, nickel, cadmium, zinc, selenium, and cobalt, are rapidly removed from surface water by sinking tissue, but redissolved when the tissue is oxidized in the deep sea. They remain in the oceans for 103-105y before their final removal into the sediments. Selenium and chromium are present in the dissolved form in two oxidation states, while manganese and iron are rapidly scavenged once the reduced species are oxidized. The ocean's sources of trace elements - input from rivers, submarine hydrothermal processes (at least for manganese), and dissolution from aerosols (for manganese, lead, and copper among other elements) - are fairly well known. The removal mechanisms are less well understood, although it is clear that burial

of trace metals carried to the sediments by falling tissue is the dominant process.

Most of our understanding of the marine cycles of trace metals is based on concentration variations in seawater. Such data cannot, however, give us a profound understanding of the physical chemistry governing their behavior. To meet this problem, some groups have studied the inorganic ion pairing reactions of the trace metals, metal-organic interactions, and the reactions between trace metals and important inorganic and organic surfaceactive phases. Other groups are studying trace metal behavior by radiolabelling trace metals in enclosed ecosystems, and determining their uptake rates and solid phase distributions.

The rare earth elements (REE) have a unique role to play in extending our understanding of marine trace metal geochemistry. Their ionic radii, and hence ion pairing and surface adsorption stability constants, vary in a predictable way with atomic number. As a consequence the importance of complex formation and adsorption in the marine cycles may be inferred directly from the subtle interelement differences in REE distributions. While all REE exist in the +3 oxidation state, Ce and Eu also exist in the +4 and +2 oxidation states, respectively. By comparing their distributions with those of adjacent rare earths, it is possible to judge how their behavior depends on oxidation state. The relative abundances of rare earth elements are distinctly different in various continental source materials, seawater, and sediments and the abundance patterns can serve as 'fingerprints' that identify sources of the elements in seawater, sediments, and manganese nodules. The isotope composition of one of the REE's, neodymium, itself serves as a fingerprint, since it varies in different source rocks as a result of Sm radiodecay to Nd143. Finally, the power of all these tools for studying REE chemistry is enhanced, as Elderfield and Greaves show, by two happy coincidences. First, REE are affected by nearly all of the important processes influencing marine trace metal behavior: atmospheric input, adsorption and scavenging onto falling particles, coprecipitation, ion pairing, and redox reactions. Second, the scavenging residence time for REE - apparently about 400y - is shorter than the oceanic mixing time (1,600y), so that REE and Nd isotopes always reflect elemental sources. If the residence time were longer than the mixing time, the fingerprinting would be less distinct and the REE studies would be less useful.

The second trend reflected in Elderfield and Greaves article can be seen in a number of recent papers. Pb isotopes are now being used to trace the anthropogenic lead distribution, while Sr isotopes are being used to study low and high temperature seawater-basalt exchange as well as

carbonate diagenesis. Elderfield et al. (Geochim, cosmochim, Acta 45, 1231; 1981) used REE distributions to characterize the source of these elements in North Pacific nodules and sediments. Goldstein and O'Nions (Nature 292, 3241; 1981) have used the strontium and neodymium isotope compositions to show that, in manganese nodules, those elements have been precipitated from seawater, while Piepgras and Wasserburg (Earth planet, Sci. Lett. 50, 128; 1981) have shown that the isotope composition of dissolved neodymium is different in the Atlantic and Pacific oceans (indicating a residence time less than the mixing time).

Rare earth concentrations in seawater were first measured successfully in a few samples during the sixties by Goldberg et al. (J. geophys. Res. 68, 4209; 1963) and Høgdahl et al. (Adv. Chem. Ser. 73, 308; 1968.) Since then only a small amount of additional data has been published. The

paper by Elderfield and Greaves represents a major advance in the accuracy of measurement, and through the study of a complete water column profile allows an appreciation of the roles of particles in removing REE from the shallow waters of the ocean and remineralization redissolving them at depth.

The data allows Elderfield and Greaves to outline the main aspects of both the long term mass balance of REE in the oceans, and the pathways involved in the internal cycling of REE. The context is thus set for more detailed studies of the oceanic distributions of the REE. The results promise to give us a profound understanding of the mass balance, internal cycling, and physical chemistry of REE's in seawater, and thereby greatly extend our appreciation of how the fundamental chemical properties of trace metals influence their behavior in the marine environment.

100 years ago THE CHANNEL TUNNEL

The two schemes for a tunnel beneath the Channel, on the comparative merits of which a Parliamentary Committee will probably take evidence in the course of the year, are based, like those which have preceded them, chiefly on geological considerations. The Weald of Kent and the Bas-Boulonnais, once in all probability geographically continuous, still constitute a single geological area.

The two schemes which are offered for tunnelling through the Chalk may be briefly stated as follows:—

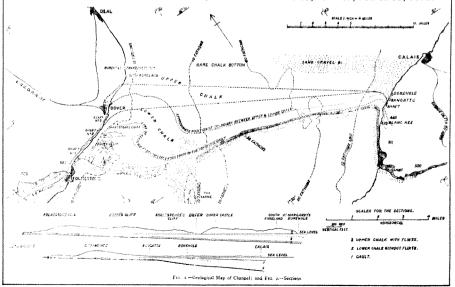

1. The Channel Tunnel Company, with which Sir John Hawkshaw is connected, propose a tunnel starting from Biggin Street, Dover, with a gradient of 1 in 80, passing under the north spur of Dover Castle Hill, and thence continuing to a point on the shore known as the Fan Hole at a distance of 2 miles, 4

furlongs, 2150 chains from Biggin Street, and at a depth of 115 feet below high water ordinary spring tides. From this point it will run across the straits to join the French tunnel, which commences near Sangatte, and as Sir J. Hawkshaw has always advocated a straight line of tunnel, we presume that such will be the case here.

2. The Submarine Continental Railway Company, with which Sir E. Watkin is associated, propose a tunnel connected with the South-Eastern Railway, about two furlongs west of Folkestone entrance of the Abbotscliff Tunnel by a tunnel descending at a gradient of 1 in 52 to the bottom of the No.2 Shaft, near the west end of the Shakespeare Tunnel, at a depth of 126 feet below high water ordinary spring tides. From this point the tunnel will continue for about a mile towards the head of the pier in a direction slightly diverging from the shore, and finally curving round, will fall into the line of the French tunnel near Sangatte.

So far as our information goes at present it seems that the most serious obstacle will be water, and it is therefore on their relative liability to flooding that the proposed tunnels must be judged.

REVIEW ARTICLE

The map sense of pigeons

James L. Gould

Department of Biology, Princeton University, Princeton, New Jersey 08544, USA

Homing pigeons are able to return to their lofts after displacement to unfamiliar sites hundreds of kilometres away. A map sense enables them to determine their location, and a hierarchy of compass senses orient their flight. Recent experiments implicate magnetic and olfactory cues as the basis of the mysterious map sense.

HOMING pigeons can be taken from their lofts and transported hundreds of kilometres in covered cages to unfamiliar sites and yet, when released, be able to choose fairly accurate homeward bearings within a minute and fly home. From direct tracking we know that a homing pigeon typically circles near the release site once or twice, edging in the general direction of home, and then straightens out and flies off at nearly the correct bearing1 (Fig. 1a). At most sites the usual vanishing bearing—the direction in which the bird is lost to view or, if it is carrying a radio transmitter, in which its signal fades out-is reliably left or right of the true home bearing. This consistent deviation is known as 'release-site bias' 2,3 since it varies from site to site (see Fig. 1b) or as 'preferred direction' 4,5 since it seems to impose a fairly consistent directional tendency onto the homeward direction of birds from any one loft (NNW in Fig. 1b). However, the exact route home is quite variable, and even the same bird released time and time again from the same site never seems to fly the same route twice. Once near home pigeons rely on visual landmarks to reach the loft⁶. Detailed vision is not necessary until the very last stages of the homing process, however, since birds wearing frosted lenses can get to within a few kilometres of home⁷ (Fig. 1c). Moreover, pigeons can even be trained (though with great difficulty and high attrition) to home at night8. Pigeons are not unique in their ability to locate precise targets from great distances—animals as diverse as monarch butterflies and sea turtles perform similar feats as part of their normal migratory repertoire—but the willingness of the pigeon to home on demand, day after day, has made it the favoured vertebrate for navigational research.

Aside from reading the minds of the experimenters (a possibility which has not escaped investigation), there are only three basic explanations for the remarkable ability of pigeons to home⁹: (1) the birds might keep track of their outward displacement (the system of many short-range species such as honey bees); (2) they might follow some home-centred gradient to their goal; or (3) they might have a true map sense which would permit them to 'place' themselves with respect to home on some internalized coordinate system.

For pigeons (and probably most other wide-ranging animals) the first two alternatives seem unlikely. If pigeons had to measure their displacement (presumably by keeping track of the direction and degree of acceleration and deceleration of the various turns, and timing the individual legs of the journey), simply transporting them in the dark or with constant rotations ought to impair or eliminate their ability to orient. This treatment, however, has no effect¹⁰⁻¹², nor does transport under complete anesthesia^{10,13,14}, or bisection or surgical removal of the vestibular apparatus¹⁵⁻¹⁹. Another model for an inertial system might involve a magnetic compass to measure the direction of each leg of a journey, and a time sense to estimate the length of each part. Birds transported to the release site wearing magnets or otherwise subjected to an artificial magnetic field, however, are often not affected (refs 8, 11, 12; but see below). Unfortunately, no one has yet performed the crucial experiment of transporting pigeons in total darkness anesthetized, rotating, and with the field reversed all at the same time.

The gradient alternative is also entirely lacking in experimental support. Such a strategy, based as it is on a 'getting warmer' system of movement, requires no compass sense. Yet pigeons have been shown to have compasses and to depend on them for homing; as we shall see, birds may be made to fly directly away from home by such relatively simple manipulations of their compass sense as clock shifts.

The compass sense

The idea that pigeons must have both map and compass was first put forward by Kramer²⁰. As he pointed out, an animal transported to an unfamiliar site probably needs both: a map sense to determine the direction of displacement from home, and a compass to find that direction. (In theory, of course, a pigeon could home by means of successive map readings without any recourse to a compass; but the clock shifts described below, as well as the ability of the birds to select a reasonably accurate homeward bearing within 100-500 m of the release site, render this possibility extremely unlikely.) Kramer demonstrated that the usual daytime compass of birds is the Sun. He trained starlings21 (and subsequently a variety of other birds including pigeons²²) which had a view of the natural Sun to seek food in a specific compass direction, and they readily learned to perform all day long. Apparently the birds could compensate for the Sun's westward movement in the sky. When Kramer deflected the Sun's image with mirrors, the birds were reoriented in the concomitant direction. Finally, when Hoffmann shifted the circadian rhythm of his birds—so that subjective dawn was at noon, say-the birds misread the Sun's azimuth accordingly2 Extensive work with clock-shifted pigeons in the field has confirmed that their preferred daytime compass is solar: a bird shifted by 6 hours will depart from a release site roughly 90° off the homeward bearing on a sunny day²⁴⁻²⁶.

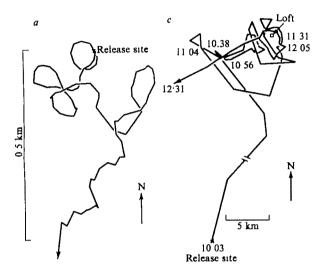

Keeton found that clock-shifted pigeons orient and home normally under overcast skies²⁵; this raises the possibility that rather than using celestial cues perceived through the clouds, they must utilize some back-up compass. Merkel and his colleagues had already shown an exceedingly weak but persistent ability in caged migrants to orient appropriately to the Earth's magnetic field^{27,28}. Keeton discovered that pigeons carrying magnets on their upper backs could orient normally on sunny days, but usually not under overcast skies²⁹. Walcott and Green³⁰, using pigeons equipped with miniature Helmholtz coils on their heads, were able to extend Keeton's results, lending support to the Wiltschkos' suggestion (based on caged migratory robins³¹) that 'north' for pigeons is the direction of the dip lines into the Earth independent of actual magnetic polarity. Given the crucial importance of this 'dip-angle' hypothesis it is remarkable that the Wiltschkos' experiment has not been repeated. Walcott's basic results have been replicated by Visalberghi and Alleva³²

More recently, the Wiltschkos have followed up Keeton's finding that young birds wearing magnets on their first flights cannot orient even with a full view of the Sun²⁹. They have discovered that the Sun compass system must first be calibrated

against the magnetic compass³³. Hence, pigeons kept under permanent clock shift since birth are able to orient and home perfectly well, but are misoriented after being reset to normal time³⁴. The emerging picture of the pigeon compass, then, is that the magnetic sense is innate—based perhaps on the deposits of magnetite recently discovered in pigeons^{35,36} and other navigating species—and is used to calibrate a time-compensated Sun compass³⁴. Having served as an essential reference, the magnetic compass sense seems to be largely or completely ignored whenever solar information is available. A very similar pattern of calibration has now been documented in the ontogeny of orientation in nocturnal migrants³⁷⁻³⁹.

The map sense

In sharp contrast to the steady progress in our understanding of the nuts and bolts of the pigeon compasses, the map sense of

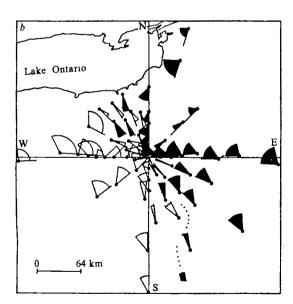

Fig. 1 Behaviour of pigeons while homing. a, After release, pigeons typically circle briefly and then fly off in the general direction of home. b, Release site biases near Ithaca (centre of grid). The mean bearings of pigeons deviate reliably from the homeward direction at almost all locations. There is a strong tendency for the biases of birds released near Ithaca to be clockwise (black) to the east and counter-clockwise (white) to the west of a line running roughly NNW through Ithaca. c, Once near home, pigeons generally use visual landmarks. In this case, however, the bird was wearing frosted contact lenses and so was unable to locate the loft more precisely than a few kilometres. This probably represents the limit of resolution in the pigeon map system. Data from (a) Elsner¹, (b) Windsor², (c) Schmidt-Koenig and Walcott⁷.

these birds has proven exceedingly difficult to elucidate. The first serious theory was put forward by Yeagley^{40,41}. He imagined that pigeons determine their location by means of a bicoordinate grid of magnetic field intensity and Coriolis force. Since the north magnetic pole is about 2,300 km from the north geographic pole (the axis of rotation), the isolines of vertical magnetic field strength and Coriolis forces intersect at about a 30° angle in the northeastern United States. Yeagley's hypothesis has been discounted on both experimental and theoretical grounds⁴².

The second major effort to explain the pigeon's map sense was by Matthews^{43,44}. He proposed that birds could use the Sun's elevation and arc (which they would extrapolate through the sky on the basis of its motion over a brief interval) in combination with their own internal time sense. A pigeon taken south-west, for example, will find the Sun's position unusually high and east (which is to say early) by an amount corresponding to its displacement from the loft. As a compass, the pigeon could use the extrapolated highest point in the arc as a measure of south. A variety of simple observations have made this 'Sun arc' hypothesis seem very unlikely. The two most compelling are the ability of pigeons to home under overcast25 and the birds' consistent interpretation of clock shifts as compass rotations and never as map displacements²⁴⁻²⁶. Hence a pigeon clock-shifted 6 hours early and released at local dawn when its internal clock reads 'noon' ought, according to Matthews, to presume it has been taken a quarter of the way around the world to the west. Such an animal ought to fly east. Instead, it will inevitably depart 90° left of home—west if it has been taken south. Despite its lack of supporting evidence, however, Matthews' hypothesis with its explicit, testable predictions has been the single most important element contributing to our present understanding of both maps and compasses.

At present there are two main map hypotheses, one based on olfaction, the other on magnetism. Both schools of thought offer intriguing and apparently reasonable experimental evidence, and yet neither can, as yet, satisfactorily explain the behaviour of pigeons.

Olfactory maps

The olfaction hypothesis grew out of a curious set of 'palisade' experiments begun by Kramer⁴⁵ and continued by Wallraff⁴⁶ The usual protocol for raising homing pigeons for research is to allow the birds a free view of their surroundings from the loft (presumed to be important for calibration of the celestial compass) combined with daily exercise flights in the immediate vicinity of the loft to build endurance. Finally the birds are taken ever further from the loft for a series of practice releases before testing at longer distances. The practice releases help weed out poor homers. In the palisade experiments, however, the pigeons are never allowed exercise flights or practice releases. As a result, the birds' first release in palisade experiments is usually also their last; such a small proportion is ever found again that data on the directions in which they are found should be discarded. Only the vanishing bearing results can be considered very reliable.

The essential result of the original palisade experiments was that blocking a view of the horizon and the lowest 3° of the sky with wood or even clear glass resulted in birds less well oriented than those permitted an unobstructed view of the Sun, sky and horizon. Blocking the view of the sky with a roof down to just a few degrees above the horizon (and obscuring even that near dawn and dusk to prevent any direct view of the Sun) gave intermediate results (Fig. 2). The conclusion Wallraff drew from these first experiments was that there must be some non-visual "substrate of information spreading in the horizontal plane which is important for homing".

From data derived from later experiments, Wallraff concluded that birds in cages surrounded by opaque plastic louvres which were supposed to block visual cues but permit air to flow through freely were well oriented⁴⁷, but the original data (with the sporadic recoveries omitted) suggest just the opposite

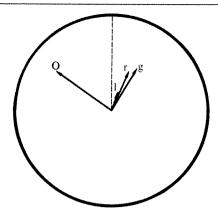

Fig. 2 Results of palisade experiments. By convention, the dashed line is the homeward direction, while the vectors describe the mean angle and degree of scatter among the birds. A vector reaching the circle would represent perfect orientation whereas a vector with no length would correspond to perfectly random data. O, pigeons raised in an open wire aviary (fairly well oriented); r, birds reared in a roofed palisade (well oriented but more scattered); g, pigeons kept in a glass palisade (fairly well oriented but scattered); l, birds raised in a louvred palisade (poorly oriented and highly scattered). Data from Wallraff 46,47.

(Fig. 2). Nevertheless those data, taken together with a recent series of elaborate louvred loft experiments⁴⁸ have been interpreted by Wallraff as implicating an 'atmospheric factor'. In these more recent tests birds in (1) a completely exposed caged loft (the controls) were compared to those raised in lofts surrounded to 10° above the horizon by (2) clear glass, (3) opaque plastic louvres, (4) clear glass on two opposite sides with the other two sides open or (5) wood on two sides and opaque plastic louvres on the other two. Wallraff's conclusion was that birds in lofts with a free flow of air (the controls and loft types 3, 4 and 5) orient better than birds in the loft surrounded by glass. The data in this highly regarded set of experiments are confusing at best, and are made all the more so by the lumping together of bearings at 20 seconds, 40 seconds and at vanishing time after release, and the exclusion of birds judged to be flying too low or not far enough away. Most other researchers consider only vanishing bearings to be reliable. Furthermore Wallraff lumps data from four different release sites with extraordinary release-site biases (based on control releases) ranging from 84° right of home to 149° left. The only procedure by which the confounding effect of these biases can be sorted out is to refer the experimental data to the (very limited set of) control bearings on a site-by-site basis (Table 1). On this basis it seems obvious that both the glass and louvred lofts increase the scatter of departure bearings but have little effect on net homeward orientation. The hybrid lofts, on the other hand, severely disorient their occupants. There is no pattern to the effect even when the direction of the louvred axis is compared to releases along or orthogonal to that axis (see below). In sum, then, Wallraff has shown an extraordinary and mysterious synergism between louvres and wood as well as between glass and open sides. These effects are generally interpreted as disrupting the pigeon map sense. As pointed out below, however, a compass effect is at least as likely to be the explanation, and these releases need to be repeated under overcast skies to see if it is the Sun compass that is being affected.

Despite the many inconsistencies in the various palisade experiments, Papi has followed up the seemingly obvious interpretation that the hypothetical 'horizontal, atmospheric factor' might be odour. Papi and his colleagues believe that birds come to associate the odours borne on the wind with the direction in which the wind is blowing, and so slowly build up an olfactory map of their surroundings⁴⁹. When transported to a release site, then, they have only to sniff the air en route and/or at the site to know the direction of home. Hence the louvred palisades ought not to affect orientation while glass ones might.

How odour could be used by naive pigeons at long distances (hundreds or thousands of kilometres), however, remains a total

mystery^{8,19}. Nevertheless, Papi has conducted a long and ingenious series of highly varied experiments whose results readily lend themselves to this olfaction hypothesis: (1) pigeons whose nostrils have been plugged⁵⁰ or whose olfactory nerves have been cut^{51,52} are poorly oriented at release and home slowly; (2) pigeons taken by different circuitous routes to release sites depart in directions slightly favouring the general direction of the particular detour to which they were subjected^{51,53}; (3) pigeons raised with two different artificial odours added to the wind, one from each of two different directions, and then released with one of the odours applied to their nostrils, are deflected from home as though the direction from which they were released corresponded to the direction from which the odour was carried to them in the loft⁵⁴; (4) the release bearings of pigeons raised in 'deflector' lofts (Fig. 3) whose clear glass or plastic deflectors rotate the incoming wind either clockwise or counter-clockwise are similarly rotated^{55,56}; (5) applying a strong odour to the nostrils to block the perception of local odours disorients the pigeons at release⁵⁷; and (6) the vanishing bearings of pigeons raised in lofts rigged with fans to reverse the natural direction of air flow are either roughly reversed or highly scattered58.

Problems with the olfactory hypothesis

Taken together, Papi's data seem almost overwhelming. Nevertheless, most of the experiments admit of simpler, nonolfactory explanations, or cannot be repeated, or both. One of the problems with the hypothesis comes from the failure of Schmidt-Koenig and Phillips⁵⁹ to detect any ability in pigeons to distinguish natural air (presumably laden with olfactory map information) from pure, filtered air. The technique they used, cardiac conditioning, is extraordinarily sensitive, and has been successfully used in the past to reveal the sensitivity of pigeons to UV light⁶⁰, infrasonic sounds⁶¹, minute differences in air pressure⁶², and polarized light⁶³, though oddly enough it has never succeeded in picking up any sensitivy to magnetic fields (see, for example, ref. 62). Keeton and his colleagues⁶⁴ have repeated the nerve sectioning experiments but found little or no effects on initial orientation. Indeed, when Benevenuti, one of Papi's colleagues, attempted to repeat the experiment, no effect on initial orientation was evident, though homing speed was slower65.

More recently Wallraff⁶⁶ also found that nerve-sectioned birds were less well oriented and slower to home than untreated birds. However, in none of these many experiments by the various groups was homeward orientation abolished. In Wallraff's extensive study, for example, the average mean vector length was an impressive 0.8 for controls, but still a respectable 0.4 for experimentals. Moreover, the orientation of nerve-sectioned birds differed from the controls by only 38° on

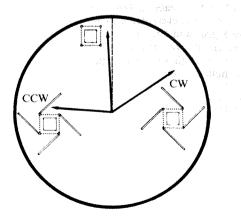

Fig. 3 Design and effect of deflector lofts. The departure bearings of pigeons kept for at least a few weeks in deflector lofts are rotated from those of controls in the same direction as the wind entering the loft is deflected. CW, clockwise loft; CCW, counter-clockwise loft. Data from Baldaccini et al.⁵⁵.

average, while groups of controls at the same sites in two different series of releases differed from each other by 41°. In short, these effects are clearly quantitative rather than qualitative, and probably have nothing to do with destroying the map system per se. Indeed, tracking reveals that the few birds in these experiments usually land and probably spend extended periods grounded⁶⁴, in contrast to the disoriented birds in other experiments who continue gamely flying. It seems likely that the behaviour of both the nostril-plugged and nerve-sectioned birds results from a generalized, distracting trauma. Indeed, when Keeton used nasal tubes to bypass the olfactory chamber and minimize trauma, no disorientation was evident⁶⁷. Moreover, both Schmidt-Koenig and Phillips⁵⁹ as well as Kiepenheuer⁶⁸ have shown that when the olfactory epithelium of a pigeon is sprayed with the potent local anaesthetic xylocaine, initial orientation is normal. Experiments with cardiac conditioning demonstrate that xylocaine-treated birds are unable to respond even to strong artificial odours for about 90 min after treatment⁵⁹.

Papi's detour experiments have also proven difficult to replicate. Keeton^{64,69} found no real effect in almost all cases while Schmidt-Koenig and his colleagues drew a blank in 11 of 12 tries⁷⁰. At the rare sites showing an effect, however, the deflection was relatively consistent. Of course the olfaction hypothesis is by no means the only explanation for a detour effect. Similarly, neither Keeton's group ^{64,71} nor Schmidt-Koenig's⁷⁰ could find that applying masking odours to the beaks and nostrils of pigeons had any predictable effect.

Of all the non-surgical manipulations reported by Papi's group, only the deflector loft has worked consistently elsewhere. Both Kiepenheuer⁷² and Keeton's group^{73,74} have obtained consistent rotations of departure bearings, but there seems no reason to suppose that these dramatic effects have anything to do with odour. Wallraff, for example, has pointed out that the results from his many louvred palisade experiments contradict the olfaction hypothesis. In the heroic series of experiments summarized in Table 1, releases from along the axis of the louvres or open ends of loft types 4 and 5 ought to have yielded far better orientation than releases from along the orthogonal axis. In fact, there was no difference: the mean vector length and angular error for on-axis releases was 0.47 and 99° versus 0.45 and 99° off-axis⁴⁸. Similarly, Kiepenheuer found the deflector lofts worked just as well on birds with plugged nostrils or with xylocaine treatment⁶⁸, implying that the deflection is not a result of rotated windborne odours.

The greatest difficulties with both the palisade and deflector loft experiments arise from the uncontrolled effects that the various clear and opaque plastic and glass elements certainly have on the transmitted and/or reflected UV and polarized light which pigeons perceive. The UV-polarized light of the blue sky is well known to be of supreme importance in the orientation of a variety of animals, most notably the honey bee, and all of the various plastic and glass elements are opaque to UV and greatly alter the degree and direction of polarization. Even more problematical are the reflections each would inevitably generate. Following up on these worries and the suspicious observation that the deflector effect is very slight or even absent under

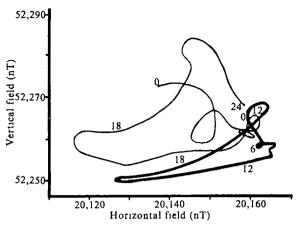

Fig. 4 Daily patterns of magnetic field intensity. On normal days (heavy line) the pattern is relatively regular. (The numbers by the curves are hours GMT.) On 'stormy' days, however, the pattern is irregular (thin line). These curves are based on hourly means recorded by the US Coast and Geodedic Survey and Fredricksburg, Virginia in September 1973. The hourly means suppress the frequent but brief 100 nT pulses which accompanied this storm.

overcast skies, two of Keeton's colleagues, Waldvogel and Phillips, designed a clever deflector loft which rotates wind one direction while it reflects incoming visual cues the other way. The release bearings of the pigeons raised in these lofts are strongly rotated in accordance with the visual cues, demonstrating that the rotation of visual cues is more important in creating the phenomenon⁷⁵. Hence, the deflector loft effect is probably a recalibration of the pigeon compass rather than of the map sense.

A more detailed look at these new data⁷⁵ makes it clear that, as Kramer and Wallraff had already shown, no direct view of the Sun (or its reflection) is necessary for recalibration. This observation points to the probable use of polarized light, perhaps along the lines described by Brines⁷⁶. The most likely calibration component would be the prominent band of horizontal polarization which defines the solar and antisolar meridian, and which Brines and Gould have found to play an important role in bee navigation^{77–79}. Similarly, Able has found that when nocturnal migrants calibrate their compasses at dusk for their upcoming flight, altering the skylight polarization above them rotates the birds' compasses⁸⁰. It seems likely, then, that polarization patterns, so long known to be crucial to the orientation of invertebrates, amphibians, and fish, play a hitherto unappreciated role in birds.

The olfactory hypothesis, though initially very exciting, has lost some of its lustre as a result of these many problems. It may yet turn out to be true, and two experiments—training pigeons to strong, artificial odours in the loft⁵⁴, and reversing the natural wind direction in the loft⁵⁸—still stand. Even here, however, doubts intrude: (1) no one has yet repeated either; (2) Papi found that homing speeds in the strong-odour experiment were unaffected⁵⁴; (3) even Papi's group finds that rearing birds with no olfactory experience whatsoever does not affect initial orientation⁸¹; and finally (4) the maze of 'clear' plastic and glass used to construct these elaborate lofts must introduce just the sort of visual problems which may well account for the deflector effect. Of course there remains the possibility that Italian homing pigeons have a map system altogether different from that of German and American birds; and strain-specific differences in homing performance and initial orientation are well known (W. T. Keeton, personal communication). However, neither Kiepenhauer⁷² nor Wallraff^{11,12} have been able to find any major or consistent differences in orientation between German and Italian pigeons.

Magnetic maps

The major alternative to the olfaction hypothesis at the moment, put forward independently by Walcott⁸², Gould⁹, and Moore⁸³,

is based on the gradual and basically regular change in the dip angle and strength of the Earth's magnetic field. The field strength of the Earth at 40°N latitude in the US is about 0.5 G (50,000 nT). The field has several sources: by far the strongest is generated by the Earth's core, while a much weaker effect arises inductively from the movement of ions around the Earth by the jet streams. Because the daily heating and cooling of the atmosphere displaces the jet streams north and south, a moreor-less regular circadian variation of 30-50 nT is observed on the ground (Fig. 4). The total magnetic field of the Earth in the northeastern United States increases at about 3-5 nT km⁻¹ to the NNW, the vertical strength rises roughly twice as fast, and the dip angle increases at about 0.01° per km.

To account for the accuracy displayed by pigeons wearing frosted contact lenses⁷, a seemingly impossible sensitivity of 10-30 nT or 0.03° would be necessary; but just such sensitivities can be inferred from the behaviour of birds. After solar flares, for example, enormous numbers of extra ions appear in the jet streams, causing irregular changes in the strength of the Earth's field ranging from 10 to 1,000 nT (Fig. 4). These 'storms' have roughly dosage-dependent effects on birds⁸⁴. For example, the release-site bias of Ithaca pigeons released at Campbell, New York, is rotated up to 40° counter-clockwise (in addition to the usual 12° bias) during moderate storms (Fig. 5a). (Regrettably, no data on how scattered the birds' vanishing bearings were during such storms has been published.) A retrospective analysis of 18 years of homing pigeons races in Italy 85,86 confirms a strong negative correlation between homing speed and the sunspot activity which is responsible for such storms, and Yeagley pointed out a similar relationship in American races⁴². Similarly, Moore observed that the increasing levels of magnetic storm activity increased the angular deviation of free-flying nocturnal migrants⁸⁷, while Southern found a substantial effect on the orientation of gull chicks88. These various observations imply a sensitivity of 10-30 nT. Since even a 1,000 nT storm could not, in the most extreme conditions, rotate a compass needle even 2°. and since the effects on pigeons and gulls are observed when the sun is clearly visible, the phenomenon is more likely to be related to the map sense.

Although the effects of solar activity on pigeon orientation are well documented and intriguing, naturally occurring variations in magnetic topography provide a static and therefore more convenient index to magnetic sensitivity. To use a magnetic map, pigeons would have to extrapolate the local rate and direction of magnetic gradients (inferred either during exercise flights or during transport to the release site) in order to judge the distance and direction of displacement. Hence any slight nonlinearity in values at the loft ought to result in a vague but

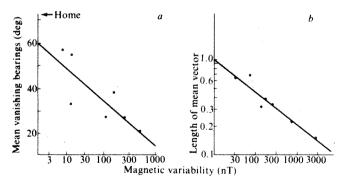

Fig. 5 Effect of small magnetic field disturbances on homing pigeons. a, Birds released at Campbell, New York normally show a site bias of 12° CCW. This bias is exaggerated during magnetic storms. Storm data represents a 12-hour average of the most active magnetic component as recorded at Fredricksburg. Data from Keeton et al. 84. b, Vanishing bearings of birds released at magnetic anomalies are more scattered in proportion to the strength of the anomaly. The data, from Walcott 89, are based on the magnetic variability in the homeward direction over the first kilometre.

systematic pattern of errors at release sites (imposed, of course, on any site-specific deviations) roughly aligned with the general direction of the regional magnetic gradients. This seems to be the case. Figure 1b, for example, reveals a pronounced tendency for site biases around Ithaca to be clockwise east of the NNW line of magnetic field gradients, and counter-clockwise to the west. It is as though 'pigeon' Ithaca is NNW of geographic Ithaca. Similarly, the pattern of biases around Schmidt-Koenig's former loft at Frankfurt (where the gradient runs west) and several locations mapped by Wallraff consistently fall into this pattern. As would be expected in some cases (one of Wallraff's as well as Walcott's loft in Lincoln, Massachusetts), the clockwise/counter-clockwise pattern is reversed as though the loft is magnetically south of its true location along the axis of the regional field gradients.

The Earth's magnetic field also has permanent localized anomalies, generally created by areas of high magnetic permeability such as iron deposits. These provide a favourable path for magnetic lines of force, concentrating the lines and thereby raising the local field strength. Walcott has carried out an extensive series of releases at anomalies of various strengths and finds a clear relationship between the magnitude of the anomaly and the degree of scatter in vanishing bearings (Fig. $(5b)^{89}$. Tracking of birds from normal (Fig. 6a) and anomalous sites (Fig. 6b) on sunny days illustrates the dramatic and longlasting nature of the effect. It seems clear that these small irregularities in magnetic field strength leave birds with almost no idea of where they are; and the persistence of the effect for a time after they have escaped from the anomaly suggests a time-averaging processing strategy similar to that of bees⁹¹. It is also worth noting that the 10-30 nT level at which effects begin to be evident corresponds to the predicted threshold for a magnetic map sense based on the accuracy displayed by the birds wearing frosted lenses⁷.

Along the same lines Wagner ^{92,93} has found a strong tendency for pigeons to respond to magnetic slopes of about 30 nT km⁻¹. His birds flew down slopes regardless of home direction—a sensible strategy since gradients of more than 5 nT km⁻¹ indicate an anomaly—and, since virtually all anomalies are the result of elevated local field strength, down is almost always the way out to the magnetic 'plains' where more reliable map readings would be possible (see Fig. 6). (Similar though less well documented effects of magnetic topography have been reported by both Talkington ⁹⁴ and Graue ⁹⁵.) Moreover, such a 'fly-down' strategy could explain the mysterious difficulty of nearly all Ithaca pigeons to orient accurately at the Jersey Hill fire tower in western New York state. The few birds which have been tracked from aircraft wander about within a few kilometres tracing out the limits of what is, to a first approximation, a magnetic 'valley'.

Further suggestive evidence in favour of a magnetic map sense comes from three diverse sets of experiments by Kiepenheuer⁹⁶, Wiltschko's group⁹⁷, and even Papi and his colleagues⁹⁸. In each case an alteration of the magnetic field felt by the birds on the way to the release site resulted in a significant change in orientation. These recent results are in marked contrast to older experiments (cited earlier) with less completely controlled fields which found no effect. The exact reason for these differences is not clear.

Problems with the magnetic hypothesis

Encouraging as all these data seem, the magnetic map hypothesis faces severe problems. The first is that two axes are needed for bicoordinate navigation. The magnetic parameters available are total field strength, vertical strength, horizontal strength, declination (the deviation of the horizontal vector from true north), and inclination (the dip angle). Declination is useless since it requires knowing true north at the release site even under overcast skies; and both inclination and total field strength use up the same two components: vertical and horizontal strength. Hence, birds would have either to compare horizontal against vertical or total field strength which would form a grid in the northeastern United States intersecting at

about 20°. If pigeons were using such a grid, then departures ought to be more accurate and less scattered to the ENE and WSW. In fact, only a slight trend of this sort is apparent in the data. Of the two other possibilities, total intensity and dip angle (the ratio of vertical and horizontal intensities), only the latter seems likely: there are areas with large, gentle variations in field intensities—a result probably of either weak, large-scale differences in ground permeability to magnetic fields, or strong but deep anomalies—which would overwhelm any simplistic

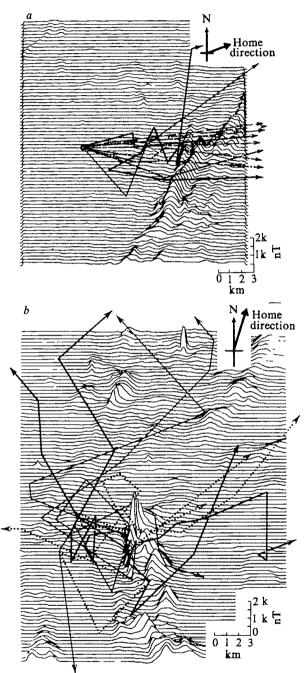

Fig. 6 Flight paths of pigeons away from release sites. Total magnetic intensity (the only parameter available from the aeromagnetic surveys by the US Geological Survey upon which these illustrations are based) increases steadily at 4 nT km⁻¹ to the NNW, creating an inclined plane. Only the anomalies in this pattern have been drawn here and are seen as 'hills'. a, Pigeons released from a magnetically normal site near Worchester, Massachusetts depart directly away, displaying the slight clockwise bias typical of this site. b, Birds released at the magnetic anomaly at Iron Mine Hill, Rhode Island, on the other hand, are thoroughly disoriented. At this site the field strength is approximately 6% high. Data from (a) Walcott (personal communication) and (b) Walcott⁸⁹; drawings from Gould⁹⁰.

attempt to make sense of regional patterns of total field intensity but which might not affect the horizontal/vertical ratio. This ratio, the inclination or dip, is precisely the measure employed for magnetic compass orientation in robins³¹ and probably pigeons³⁰. But if birds must abandon total intensity for dip, they must be able to measure true vertical—presumably gravity—as a reference angle with great precision (that is, to within 0.03°, a difficult but not impossible task). Perhaps this could help explain some of the puzzling, weak gravitational effects reported by the Keeton group⁹⁹. To further confound matters, most magnetic anomalies, created as they are by iron deposits, are gravity anomalies as well.

Another apparent problem is that strong magnets and Helmholtz coils normally do not destroy orientation on sunny days^{29,30,100}. How could pigeons possibly measure such minute field changes in the face of strong static fields? Interestingly, however, the vanishing bearings of pigeons given such strongfield treatments correspond to those seen on days of severe magnetic storms¹⁰¹—suggesting a map effect. Moreover, when Walcott released magnet-equipped pigeons at anomalies, the effect of those small geographical disturbances persisted 102 indicating that these small perturbations were being perceived through the strongly altered background. Taken together, both the data and theoretical considerations suggest that any magnetic map detector must attend solely to the small changes between and around both loft and release site, and ignore the far larger but utterly useless background field which is essential for the cloudy day compass system. A further constraint is that such a map system must have a fairly long time constant since (1) pigeons can usually fly through anomalies with little effect, (2) the birds are not disoriented by wing-mounted magnets which would create an alternating background field 38,39,103 (3) they seem less disturbed by the brief but powerful 'pulses' in magnetic field storms than by longer-term changes in background field, and (4) homing pigeons do not recover from releases at anomalies until they have been out of the field for some time (Fig. 6b).

A final problem for any magnetic map system is how the nervous system could possibly measure such small intensity variations. Although Kirschvink and Gould have shown that the vast numbers of single domains of magnetite discovered in pigeons could produce a resolution better than 1 nT¹⁰⁴, whether either these calculations or the magnetite have anything to do with pigeon navigation remains to be seen.

The real difficulties with the magnetic map hypothesis, then, are threefold. (1) It has no satisfactory explanation of the necessary second coordinate (it could be magnetism again, odour, infrasound, the Sun (though obviously not on cloudy days), or even Coriolis force). (2) It is based almost entirely on correlations rather than direct, controlled experimental manipulations (the effects of strong, artificial field alterations during transport, for example, ought to have generally unpredictable or even negligible effects). And (3) there is as yet no convincing explanation of either the sensory basis of magnetic field perception or the processing of that data to extract map information. Given the evidence for both olfactory and magnetic effects, it would be attractive to suppose that both answers are correct: perhaps, by analogy with the solar and magnetic compass of pigeons, birds can use either as the situation demands; or, both might be used simultaneously. If the first possibility were correct, we would expect that repeated releases at magnetic anomalies ought to force pigeons into using the alternative olfactory map system. However, since Walcott has released the same pigeons repeatedly at different anomalies, and such birds simply do not improve, the inference is that birds must lack an alternative system. Of the possibility that olfactory and magnetic information must be used together, one can only say that it seems at least as plausible as that they use magnetic information alone or with some unknown factor.

It is ironic that, more than three decades after Yeagley's original hypothesis, we are still largely in the dark and, for all we know, his explanation may yet turn out to have been rather close

to the mark. We probably now have nearly all the pieces of the puzzle before us (and, doubtless, several utterly irrelevant ones as well) but for the immediate future, at least, the nature of the animal map sense seems likely to retain its status as the most

Pancake detonation of stars by black holes in galactic nuclei

B. Carter & J. P. Luminet

Groupe d'Astrophysique Relativiste, Observatoire de Paris, 92190 Meudon, France

Recent efforts to understand exotic phenomena in galactic nuclei commonly postulate the presence of a massive black hole accreting gas produced by tidal or collisional disruption of stars. For black holes in the mass range 10^4 – $10^7 M_{\odot}$, individual stars penetrating well inside the Roche radius will undergo compression to a short-lived pancake configuration very similar to that produced by a high velocity symmetric collision of the kind likely to occur in the neighbourhood of black holes in the higher mass range $\geq 10^9 \, M_{\odot}$. Thermonuclear energy release ensuing in the more extreme events may be sufficient to modify substantially the working of the entire accretion process.

MANY of the most plausible models for explaining spectacular energy release phenomena in galactic nuclei are based on the release of gravitational energy by gas accreting on to a very massive central black hole¹. A likely mechanism² for providing the gas necessary to fuel such a model would be the breakup of ordinary stars, either by the Roche tidal effect in the case of a black hole with mass M below the Hills³ limit, $M \leq 10^8 \, M_{\odot}$, or else by the effect of collisions in the case of a more massive black hole with a sufficiently dense surrounding star cluster. Gas release by tidal or collisional breakup (as well as by mechanisms such as supernovae and ordinary stellar winds) may also be important at other relatively quiescent stages in the history of a galactic nucleus containing a black hole, that is at times when the most observationally spectacular phenomena (such as quasars) are absent.

This article draws attention to a neglected effect which could be significant in many situations where tidal or collisional disruption occurs, namely that in the more extreme events (which may constitute a not negligible fraction of the total) the disruption will be preceded by a short-lived phase of high compression to a roughly pancake shaped configuration in which the density and temperature may rise enough to detonate effectively some significant fraction of the available thermonuclear fuel.

A very flat pancake type configuration will be formed briefly by any nearly head-on collision between roughly similar stars at very high relative velocities (analogous pancake formation being experimentally familiar in the microscopic context of very high energy proton-proton collision). We have in mind in particular the kind of event that is likely to occur near a black hole with the very large mass $M \ge 10^9 M_{\odot}$ that is thought⁴ to be necessary to account for the most extreme quasar phenomena. Beyond 0.1 pc from such an object, typical stellar collisions will have velocities ≥10⁴ km s⁻¹, thus exceeding by a factor $\beta > 10$ the minimum of the order of 10^3 km s^{-1} needed for disruption. Detailed studies of high velocity (≥10⁴ km s⁻¹ collisions will require an elaborate hydrodynamic treatment, with allowance for shocks, of the kind already available⁵ for the intermediate velocity (≈10³ km s⁻¹) collisions in which a moderate degree of flattening is already present. However, a preliminary idea of the effects to be expected may be obtained from consideration of the simpler but otherwise very similar configuration that arises during tidal disruption of a single star, whose evolution can be followed approximately6,7 in terms only of ordinary differential equations using an adiabatic affine star model which, although highly idealized, can, nevertheless, be expected to provide a qualitatively valid description of the behaviour of the stellar core before, if not after the instant of maximum compression.

The phenomena of tidal disruption of a self gravitating body passing within the Roche radius

$$R_{\rm R} \approx M^{1/3} \rho_{\star}^{-1/3} \tag{1}$$

(where ρ_* is its characteristic central density) has been studied for over a century, but mainly in terms of an incompressible fluid model. It does not seem to have been realized that adequate allowance for compressibility leads to the prediction that a star penetrating deeply within the Roche radius will pass through a phase of compression to a highly flattened pancake configuration, closely similar, in both spatial and temporal characteristics, to that produced by a symmetric collision involving a pair of stars. It turns out that the effect of a collision with stellar velocities exceeding the central characteristic velocity (which is a few hundreds of km s⁻¹ for a typical main sequence star) by a factor of the order of β can be roughly simulated by a single star following an orbit that penetrates to within a pericentre radius R_p given in order of magnitude by

$$\beta \approx R_{\rm R}/R_{\rm p} \tag{2}$$

(a value β of the order of 10 thus being sufficient to reproduce the effect of a collision with relative velocity of the order of $10^4 \,\mathrm{km \, s^{-1}}$). Not only can the study of thermonuclear reactions in such a tidally produced pancake give a first rough indication

of what may occur in a high velocity stellar collision, but it would also appear to be an astrophysically interesting phenomenon in its own right in the context of a black hole in the moderate mass range $10^4 M_{\odot}$ to $10^7 M_{\odot}$ for which it is possible to obtain a large value of β without the star either being penetrated by or swallowed by the black hole. The potential importance of this phenomenon stems from the fact that deep penetration is much less improbable than would be expected from purely geometric considerations. Just as the probability of high velocity collisions deep in the potential well of an $M \ge 10^9 M_{\odot}$ black hole is enhanced far above what would be proportional to the corresponding volume (by an amount whose exact calculation is difficult) in consequence of the well known cusp effect in the stellar density distribution (see ref. 8), so, similarly, the probability of penetration of an individual star deep within the tidal field of a more moderate sized black hole will also be much higher than would be deduced from the corresponding purely geometrical cross-section, by an amount that can be relatively easily estimated from the characteristics of the individual approximately parabolic orbit. We conclude that the fraction of all tidally disrupted stars with penetration factor exceeding a given value β will be of the order of magnitude of β^{-1} .

Extent and duration of compression

To derive equation (2) it is sufficient to see that the tidal force on the star (which is inversely proportional to the cube of the radial distance R from the hole) will rapidly dominate the internal pressure and self-gravitational forces on the star as it begins to penetrate substantially within the Roche radius R_R (the latter being characterized by the condition that the tidal and internal forces have comparable magnitude). In these circumstances it will become a good approximation to treat the individual particles of the star as undergoing free fall in the external gravitational field on orbits of approximately parabolic form in planes all passing very nearly through the perihelion point on the centre of mass trajectory. These planes will be confined roughly within an angle

$$\alpha \approx R_{\star} (R_{\rm p} R_{\rm R})^{-1/2} \tag{3}$$

where R_* is the characteristic radius of the star in its approximately unperturbed state before passage across the Roche radius, as given in terms of the stellar mass M_* by

$$R_{*} \approx M_{*}^{1/3} \rho_{*}^{-1/3} \tag{4}$$

Thus in the centre of mass frame of the star the particles will effectively be accelerated towards the orbital plane, with maximum velocity, u say, of the order of αv where v is the orbital velocity at the pericentre, that is

$$u \approx \alpha \left(\frac{GM}{R_{\rm p}}\right)^{1/2} \tag{5}$$

Hence we immediately see that the relative velocity u of what may be described as the collision of the star with itself will have the required form

 $u \approx \beta \left(\frac{GM_{\star}}{R_{\star}}\right)^{1/2} \tag{6}$

where the factor $(GM_*/R_*)^{1/2}$ is interpretable as the characteristic velocity of sound in the core of the star.

When matter becomes sufficiently highly compressed, the free-fall treatment will, of course, cease to be valid: as the mass centre passes through the pericentre, the tidal forces, although high, will be overtaken by a very sharp last minute rise in the pressure forces, which will cause the star to bounce back towards a more isotropic configuration. Note that stellar deformation in directions in the plane of the orbit will not have had time to become important at the instant of passage through the pericentre (the 'tube of toothpaste' extrusion effect that is familiar from the incompressible case cannot have developed significantly at this stage) so the maximum degree of compression of the resulting pancake can be estimated directly from the

requirement that the kinetic energy of the 'self-collision' be entirely converted into internal energy of the gas at the instant of turn around. If this energy is predominantly thermal, as will be the case in main sequence stars, the maximum central temperature Θ_m in the pancake will be given in terms of its value Θ_{\star} in the unperturbed state of the star by

$$\Theta_{m} \approx \beta^{2} \Theta_{\star} \tag{7}$$

This formula will also be valid when the predominant internal energy is that of a non-relativistic degenerate electron gas, which scales proportionally to the non-degenerate thermal energy of the gas of positive ions. As long as the gas remains non-relativistic the corresponding maximum central density $\rho_{\rm m}$ will be given by

$$\rho_{\rm m} \approx \beta^3 \rho_{\star} \tag{8}$$

and the duration τ_m of the phase of maximum compression will be given by

$$\tau_{\rm m} \approx \beta^{-4} (G\rho_{\star})^{-1/2} \tag{9}$$

where $(G\rho_*)^{-1/2}$ is the free-fall time scale of the star (which is automatically the same as the orbital time scale at the Roche radius R_R) whose value is of the order of 10^3 s for small main sequence stars.

Although the above arguments are crude we have confirmed them (see Fig. 1) by explicit numerical integration of the equations of motion governing an affine star model (in which the constant density layers are treated as retaining an ellipsoidal form) which represents the simplest and most natural extension of the incompressible fluid model (on which most previous numerical studies of tidal forces have been based). While probably at least qualitatively adequate during the compressive phase, such a treatment can be expected to be invalidated during the phase of subsequent expansion by the effect of shocks, whose potential importance in the envelope (as opposed to the central regions with which we are concerned here) has been pointed out by Lidskii and Ozernoy⁹, who seem to have been the first to appreciate the significance of the tidal field's initial tendency to cause compression.

Thermonuclear detonation

It is evident from equation (7) that a quite modest Roche penetration factor $\beta \approx 10$ can raise the temperature of a main sequence star from its usual value $\Theta_{\rm m} \approx 2 \times 10^{9} \, {\rm K}$ to near the value $\Theta_{\rm m} \approx 2 \times 10^{9} \, {\rm K}$ at which (according to the standard formula given for example by Fowler *et al.*¹⁰) helium combustion by the triple- α reaction proceeds at a maximum rate for a given density, the relevant time scale being given (in c.g.s.) by

$$\tau_{\alpha} \approx 10^{11} (\rho_{\rm m} X_{\alpha})^{-2} \tag{10}$$

where the helium mass fraction X_{α} will have at least the cosmological value $X_{\alpha} \approx 1/4$. As the energy that can be obtained from helium combustion is only of the same order as the thermal energy (borrowed temporarily from the gravitational field) already present, the condition $\tau_{\alpha} \leqslant \tau_{\rm m}$ is all that is required for a substantial fraction of this energy to be released. As the values $X_{\alpha} \approx 1/4$ and $\beta \approx 10$ lead roughly to $\tau_{\rm m}/\tau_{\alpha} \approx 10^{-5} \rho_{\star}^{3/2}$, we see that the efficiency of helium detonation depends primarily on the central density of the star, being reasonably high only when ρ_{\star} approaches the order of 10^3 g cm⁻³. By coincidence this is roughly the upper limit for main sequence central densities, being obtained near their lower mass limit, $M_{\star} \approx 10^{-1} M_{\odot}$.

The foregoing leads us to conclude that the most favourable conditions for efficient helium detonation will occur in conceivably very numerous (see ref. 11) 'dark dwarf' stars that are just too small to reach the main sequence but which, nevertheless, maintain central temperatures $> 10^6$ at densities ranging up to 10^3 g cm⁻³ during time scales of the order of 10^9 yr (see ref. 12). To reach $\Theta_m \approx 10^9$ K such a star needs perhaps twice as large a penetration factor β as in the main sequence case (with a correspondingly halved probability), but as a result

 $\rho_{\rm m}$ will be raised from a main sequence maximum of the order of $10^6~{\rm g~cm^{-3}}$ to a value that can exceed $10^7~{\rm g~cm^{-3}}$. At such densities the degenerate electrons will enter the relativistic regime, so that equations (7)–(9) will need modification, but allowance for this seems to confirm the conclusion that $\tau_{\rm m}/\tau_{\alpha}$ attains a value of the order of 1.

The carbon-12 formed in such a detonation process will immediately undergo further processing by α -capture and proton-capture reactions (whose details depend very sensitively on M_* and β) so that the total energy release may exceed the internal binding energy of the star by a factor of the order of 10². Thus instead of forming a diffuse cloud weakly bound to the black hole as in the non-violent disruption scenario described by Hills³, the gas will be ultimately liberated from the star in the form of a cloud expanding at a rate far in excess of the velocity of escape from the black hole. Any discussion of detailed consequences is beyond the scope of this article. We mention only that the immediate effect of the pancake detonation will be to accelerate the matter orthogonally to the orbital plane, but that subsequent radioactive energy release may lead to slingshot ejection of a fraction of the matter at very high velocities in the direction opposite to that along which the star originally approaches the hole, and to the corresponding capture by the black hole of comparable fraction of the matter in very tightly bound cloud or disk, with thermal or orbital speeds $> 10^4$ km s⁻¹. It is even conceivable that a self-sustaining hot C-N-O or rapid proton capture 13 hydrogen burning process may be set off in the expanding cloud, with even more spectacular consequences, but only a careful hydrodynamic treatment with adequate treatment of shocks will be able to check this. Analysis of the overall scenario resulting from interaction of gas from many disrupted stars will be even more complicated but we can conclude that the likely detonation of a fraction of the order of 1% (arising from say a 10% fraction with sufficiently high penetration factor β , of which a less easily estimable fraction, perhaps also of the order of 10%, may lie in the susceptible mass range) will probably be sufficient to modify significantly the overall energetics of the entire gas release process. (Analogous conclusions are probably valid for the more complicated situation resulting from collisional, as opposed to tidal, disruptions in the neighbourhood of much more massive black holes: the unfavourable statistical factor resulting from the probable necessity that both participants in the collision should lie in the susceptible mass range seems likely to be compensated by the enhanced probability of very high velocities due to the cusp effect.)

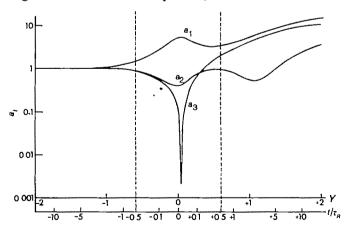

Fig. 1 The numerically calculated magnitudes of the principal axes a_1 , a_2 , a_3 (a_3 being orthogonal to the orbital plane) of a polytropic ($\gamma = 5/3$) affine (that is, ellipsoidally deformed) star model are plotted on a logarithmic scale as a function of the distance Y from the axis of a parabolic trajectory with Roche penetration factor $\beta = 10$. The corresponding time t, normalized as a fraction of the stellar oscillation time scale $\tau_R = (G\rho_*)^{-1/2}$, is indicated on a separate scale below, the approximate moments at which the star enters and leaves the Roche radius R_R being indicated by dotted lines.

Although the triple- α reaction we have been considering provides the only opening for significant thermonuclear release from the compression of population II stars (consisting almost exclusively of hydrogen and helium) it has been drawn to our attention that if the stellar population in the galactic nucleus has composition similar to that of population I stars, such as the Sun, then energy release on an individually more modest scale, but in a much larger fraction of the disrupted stars, can result from C-N-O cycle reactions. It is not possible to carry through a complete C-N-O cycle during the short lifetime of the pancake configuration because some of the steps inevitably involve slow weak decays. Nevertheless, the first highly temperature sensitive proton-capture stages (together with the later disintegration of the products) can liberate several times the binding energy of a star of solar type, if the temperature in the pancake rises above a few times 108 K. As this effect is much less density sensitive and requires a lower Roche penetration

factor ($\beta \approx 5$ would suffice) than the triple- α reaction, it will occur in a much larger fraction of the stars involved. Hence, although the individual events are much less spectacular, the total energy release from this process can (when averaged over all disrupted stars) provide a contribution to the overall energetics that is no less important than that arising from helium detonation. Indeed for a black hole near the Hills mass limit (where the larger penetration factors required for triple- α detonation are not possible) energy release from proton-capture will be the dominant contribution. The net effect will presumably be to convert the gas from the disrupted stars into an outgoing wind, leaving only a small fraction to be accreted by the hole.

The rare earth elements in seawater

Henry Elderfield & Mervyn J. Greaves

Department of Earth Sciences, University of Leeds, Leeds LS2 9JT, UK

The depth distributions of La, Ce, Nd, Sm, Eu, Gd, Dy, Er and Yb in the oceanic water column are used to evaluate the marine geochemical cycle of the rare earth elements and their application as water-mass tracers.

THE chemistry of the rare earth elements (REE) makes them particularly useful in studies of marine geochemistry. They are an extremely coherent group so that their relative abundances can be used to deduce their sources in sedimentary deposits¹. However, certain subtleties of this chemical similarity give additional important information. First, there is an ordered variation in the stability constants of REE complexes which means that the partition of rare earths between marine phases may fractionate the light relative to the heavy rare earths. Second, although the REE are predominantly trivalent there are exceptions: cerium can exist as Ce (IV) and europium as Eu (II), and these elements may fractionate from the 3+ REE as a function of redox potential. Third, some of the REE are weakly radioactive. In particular the decay of 147 Sm $(t_{1/2} =$ 1.06×10¹¹ yr) to ¹⁴³Nd coupled with the fractionation of Sm/Nd in the continental crust relative to the mantle means that the ¹⁴³Nd/¹⁴⁴Nd ratio may be used to constrain the sources

For these reasons the REE (and, recently, Nd isotopes) have been used to assess the origins and depositional environments

of modern sediments and have been used as a suite of chemical indicators of oceanic change²⁻¹². The full exploitation of such applications requires a detailed understanding of the geochemical interactions of the REE in oceans and marine deposits. Our understanding of geochemical cycles in the oceans has increased dramatically as a result of recent measurements of the distributions of certain trace elements in the oceanic water column¹³⁻²². In such cases, problems of sampling, contamination and analysis have been overcome to produce "oceanographically consistent" profiles which can be interpreted both in terms of known hydrographical and chemical features and also in terms of processes of element supply and removal such as organic matter regeneration, aeolian deposition, hydrothermal input, diffusion from bottom sediments and particle scavenging. No systematic study has yet been made of the distributions of the rare earths in the oceanic water column, the only measurements of the concentrations of the REE group in seawater being on isolated samples by Balashov²³, Goldberg²⁴ and Hogdahl²⁵ during the 1960s and by ourselves recently⁶, together with recent determinations^{7,8} of Nd and Sm. For this

reason we have determined the concentrations of nine rare earth elements in a vertical profile from the North Atlantic Ocean.

The seawater samples were collected in February 1979 during RRS Shackleton cruise 1B/79 from 28°01'N 25°59'W in the Cape-Maderia Abyssal Plain, water depth 5,250 m (also the site of GEOSECS station 115). The hydrography of the station (see also Fig. 4a) consists of a mixed layer of ~100 m, North Atlantic central water down to ~900 m, a diffuse lens of Mediterranean water with its core at ~1,200 m but influencing the potential temperature-salinity relationship to 2 km or more, below which is North Atlantic deep and bottom water. Our mass-spectrometric isotope dilution method for seawater analysis has been described previously, although some modifications have been made. Our latest analytical scheme is, briefly: the 0.4-µm filtered samples of ~501 are acidified to pH 2 and the REE spikes added. After equilibration, the REE are concentrated by co-precipitation with ferric hydroxide, separated from the sea salts by cation exchange and from Ba by mixed solvent anion exchange. They are analysed as a group in the sequence

Eu-Yb-Ce-Sm-Nd-La-Er-Dy-Gd by selective ionization (VG Isomass 54E mass spectrometer) with on-line computing²⁶. Analytical precision and accuracy determined by running standard solutions is typically $\pm 1\%$ (2σ) or better with ratios of sample REE to reagent plus column blanks of $>10^3$.

REE distribution in the oceanic water column

The REE are present at extremely low concentrations in seawater (Table 1), $\sim 10-70\times 10^{-12}$ mol kg⁻¹ for La-Nd, $\sim 0.5-1\times 10^{-12}$ mol kg⁻¹ for Eu and $\sim 3-8\times 10^{-12}$ mol kg⁻¹ for Sm-Yb. Despite these ultra-trace concentrations, factors such as contamination do not seem to have been an insurmountable problem (although some unascribable scatter is present) and the results display non-random vertical distributions (Fig. 1).

The profiles of all the REE are characterized by: (1) a deep-water enrichment, all showing significant increases in concentration towards the bottom; (2) extrema in the mid-water column ~1,000 m; (3) low but non-zero concentrations at the

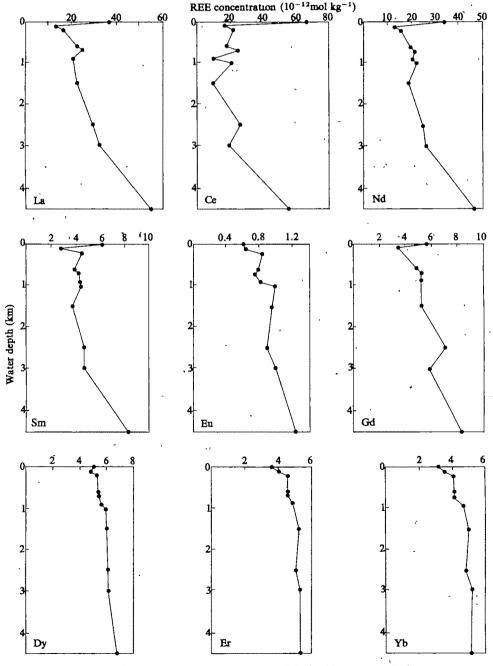

Fig. 1 Depth profiles of the REE at RRS Shackleton station 1B/79.

base of the mixed layer. In addition, the profiles of the light REE show surface maxima, that is, a surface-water enrichment:

The deep-water enrichment was suspected from earlier work¹. Some of the very early results are extremely high and must be regarded with suspicion. However, previous results^{7,8,24,25} show concentration levels similar to those reported here and include deep-water values which are higher than for shallow sample(s) from the same station. On the basis of this earlier work it has also been concluded¹ that REE levels in the deep Pacific are higher than those in the deep Atlantic. Modern data do not confirm this view. Indeed, a comparison of the most precise Nd data for the Atlantic (this study) and for the Pacific (the two analyses in refs^{7,8}) show that the Pacific values are ~30% lower at an equivalent water depth. Clearly, it is premature to make an assessment.

Table 1 also reveals that the deep-water enrichment varies in magnitude throughout the REE group in a systematic fashion. The proportional increase in concentration towards the bottom is greater for the light REE than for the heavy REE. For example, Yb-Dy are enriched by a factor of ~1.4 at 4.5-km depth relative to the base of the mixed layer (100 m) whereas Nd is enriched 3.6 times and La, 4.2 times. Like this deep-water behaviour, the surface-water enrichments of the REE vary with atomic number but with an important difference: the light REE are enriched (for example, La by a factor of 2.8 compared with the base of the mixed layer) whereas the heavy REE are not enriched or are slightly depleted. Because of their similarity, the surface-water and deep-water enrichments show a striking correlation (Fig. 2). Note that the enrichments of Ce and Eu are anomalous compared with values that may be predicted from interpolations between their respective REE neighbours. Both the fractionation of the light- from heavy-REE (or vice versa) at the surface and bottom boundaries of the water column and the anomalous behaviours of Ce and Eu are compatible with the chemistry of the REE group.

REE patterns

The shale-normalized REE pattern of seawater has been shown²⁴ to be characterized by a monotonic increase in the concentrations of the heavy REE relative to the light REE and by a marked depletion in Ce relative to its REE neighbours (that is, a negative cerium anomaly). The REE patterns obtained here may be placed in three groups (Fig. 3):

(1) The pattern for surface seawater is unlike any reported previously. The pattern is flat and shale-like with a slight negative Ce anomaly, but with a prominent negative Eu anomaly.

(2) Seawater below the mixed layer has a pattern similar to that reported previously although with a less striking Ce anomaly. With increasing depth the heavy REE enrichment becomes less significant, a negative Eu anomaly develops and the negative Ce anomaly strengthens and then weakens (Fig. 4). As a consequence, the pattern for the deepest sample

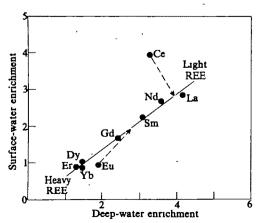

Fig. 2 Surface-water/deep-water enrichments of the REE relative to concentrations at base of the mixed layer.

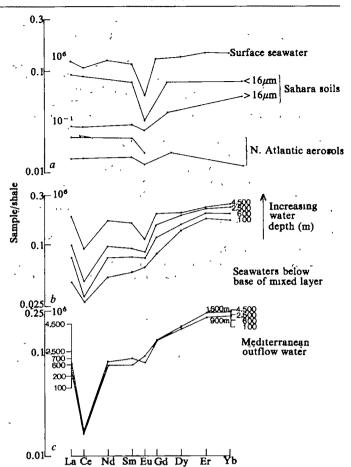

Fig. 3 REE patterns: a, surface seawater compared with Sahara soils and North Atlantic aerosols; b, seawaters below base of the mixed layer, 100-4,500 m; c, seawaters in the core of Mediterranean water, 900-1,500 m.

analysed begins to resemble that for surface seawater except for its Ce anomaly.

(3) The seawaters between \sim 900 and 1,500 m, representing Mediterranean overflow water, also show 'typical' seawater patterns but are anomalous relative to waters above and below in displaying stronger negative Ce anomalies, weaker negative Eu anomalies, and higher heavy REE and lower light REE concentrations (Fig. 3c) give a more marked heavy REE enrichment (Fig. 4).

Boundary layer processes

Because of the deep-water enrichment of the REE and the contention that REE are higher in the Pacific than the Atlantic, the REE have been likened to nitrate and phosphate and to those trace elements whose depletion in surface waters has been interpreted in terms of biological removal^{1,7,8}. From the present results it seems unlikely that the REE exhibit simple nutrient-like behaviour in seawater. Overall, the REE profiles are dissimilar to the profiles both of phosphate (which reflects near-surface regeneration of soft tissues) and of silicate (which reflects deep-water regeneration of hard skeletal materials) except that all increase with depth (Figs 1, 4). Therefore, one hypothesis is that the behaviour of the REE in waters below the mixed layer is nutrient-like, the light REE following Si and the heavy REE following P. However, the surface-water behaviour of the REE is not nutrient-like. Both silicate and phosphate show near-zero concentrations in surface waters unlike the REE. The light REE also show a significant surface maximum.

The profiles for the light REE are reminiscent of those of Cu (ref. 18) Al (ref. 21) which have been interpreted in terms of inputs across the surface and bottom boundaries of the oceans coupled with scavenging by a combination of biological removal

and general (inorganic?) removal with subsequent incorporation in and removal by zooplanktonic faecal matter or uptake on surfaces of skeletal fragments. For the REE, the association with colloidal matter such as iron-oxide flocs inside tests, or as coatings, or in biogenic particles has been favoured 10. Although we cannot yet identify any specific carrier for the REE we can show from the general depth trends of the Ree and of P, Si and alkalinity (Table 2a) that (1) planktonic material contains insufficient REE to account for the observed deep-water enrichments of the light REE (little data are available for the heavy REE); (2) REE in foraminiferal carbonate can just account for the heavy REE enrichments but not for the light REE: (3) diatom opal can readily account for all the enrichments. REE/P/Si/Ca ratios in large particles from sediment traps suggest that such material contains a large excess of REE compared with the levels needed to satisfy the deep-water enrichments. Hence, we propose that the REE are removed selectively from solution in surface waters by scavenging, the light REE being removed more effectively than the heavy REE. This process is consistent with the previously observed REE pattern for seawater which led Goldberg²⁴ to suggest that the heavy REE enrichment may be attributed either to the increasing stability of complexes of the heavier REE with seawater ligands or to their differential adsorption on solid phases. Our observations clearly indicate that Ce behaves differently from the other REE. The fractionation of the light and heavy 3+ REE is at its maximum at the base of the mixed layer (the same is true for the least negative Eu anomaly) showing that the surface removal processes are restricted to this zone (Fig. 4). In contrast, the negative Ce anomaly develops over a depth of 500 m or more, pointing to a different process, presumably the oxidation of Ce³⁺ to the less soluble 4+ valency state.

As well as REE removal in surface waters there is tentative evidence for deep-water removal. Below ~2 km where the potential temperature-salinity relationship is linear, plots of the REE against either of these conservative tracers show negative curvature, indicating removal of the REE in deep waters. However, the deep circulation of the Atlantic is complex and deep-water scavenging is not necessarily implied by this observation.

What are the causes of inputs at the surface and bottom boundary layers? Analogy with Cu and Al suggests that the bottom source is the interstitial waters of marine sediments into which the REE are released during early diagenesis when the REE-containing phases dissolve or lose their binding capacities. Again, the difficulty of modelling chemical gradients in Atlantic deep waters means that no other benthic flux need be postulated other than from regeneration. However, a sediment source is consistent with our work on oceanic ferromanganese nodules and sediments which indicates that the REE are mobile during early diagenesis ^{6,10,11}. The diffusive benthic fluxes which would

be required to maintain this deep-water enrichment are considerable—there must be strong REE gradients in the interstitial waters. Minimum benthic fluxes calculated using residence times of 100–400 yr for North Atlantic deep water are comparable in magnitude to the average rates of REE accumulation in deep-sea sediments^{1,27}. Hence, if diffusion from sediments is an important source, the uppermost layer of deep sea sediments should be strongly enriched in REE, as indeed seems to be the case for La (ref. 28). Because the cycling of the REE through the surface layer of sediments seems to be such an important part of the oceanic REE cycle it is obvious why ferromanganese nodules and coexisting sediments have the same Nd isotopic composition as deep ocean water^{7,8,10,12}. Nodules obtain Nd through sediment diagenesis which also provides the Nd in bottom waters which itself is scavenged by sedimenting particles.

The source of the surface-water enrichment relative to the bottom of the mixed layer in light REE is probably aeolian. The other trace elements for which surface-water enrichment has been observed are Cu, Mn, Pb and Al (refs 18–21). Analogy with atmospheric input tracers ²¹⁰Pb and ⁷Be which also show surface enrichment suggests that the inputs are aeolian. For the REE it is possible to employ the 'internal' tracer of the REE pattern for comparison with potential input material. This exercise (Fig. 3a) shows that the striking REE pattern for surface seawater at our station is comparable with that for Sahara Desert soils and for the North Atlantic (Sahara) marine aerosol²⁹. Nd isotope studies on the water and aerosols would be useful to confirm the interpretation but atmospheric input is probably the major source of the REE in North Atlantic surface water in this region.

Hydrographical signals

We cannot rule out the possibility that certain parts of the vertical profiles may be primarily hydrographical signals. First, the surface values could reflect advected input of continental REE and the deep-water values could mean that North Atlantic deep and bottom water forms with very high REE contents. Second, and more plausible, the mid-water extrema in the REE profiles probably reflect a distinctly different composition of Mediterranean water compared with the Atlantic water masses. Clearly, water in the Mediterranean outflow, centred at ~1,200 m at this station (Fig. 4), has a distinctive REE pattern compared with adjacent waters (Fig. 3): that is, a larger heavy REE enrichment, a more negative Ce anomaly and a less negative Eu anomaly (Fig. 4). We found the 143Nd/144Nd ratio of biogenic carbonate from the Mediterranean to be $0.512275 \pm$ 20, slightly higher than for Atlantic ratios^{7,8}. Hence, the use of REE patterns and Nd isotopic ratios as modern and palaeooceanographic tracers of water masses and ocean basins seems feasible.

The oceanic REE cycle

From sediment output##

From the above discussion we can summarize the geochemical cycle of the REE at our North Atlantic station and compute their oceanic residence times. As a first approximation we will assume a steady state and ignore horizontal transport. The major surface input appears to be atmospheric and the REE are leached from aeolian particles without significant fractionation (except possibly for Ce and Eu). The dissolved REE are scavenged from surface waters with preferential removal of the light REE. Thus, the residence time (τ) of La in the surface ocean must be less than that of Yb, the upper limit for the least reactive heavy REE being the residence time of the mixed layer $(\tau_{\rm H_2O})$ of ~20 yr (ref. 30). For typical particulate loadings in surface seawater near station 1B/79 of ~30 µg per kg (refs 31, 32) and for the enrichment of double crustal abundance of the REE in marine aerosols²⁹, there would be $\sim 7.5 \times 10^{-12}$ mol kg⁻¹ of particulate La in surface seawater if no leaching occurs at all, compared with $\sim 37 \times 10^{-12}$ mol kg⁻¹ of dissolved La. Therefore τ_{La} in surface water must be 37/7.5 times the residence time of unreactive particles ($\sim 0.2 \text{ yr}^{33}$) that is $\sim 1 \text{ yr}$, if all the REE are leached from the aeolian input. This is a minimum value for the residence time because if, say, only 15% dissolves then $\tau_{La} \sim 6$ yr. Because τ_{La} must be $<\tau_{H2O}$ then at least $\sim 5\%$ of the REE must be leached.

Another approach to estimating τ is from the REE fractionation below, relative to in, the mixed layer. As the Yb/La ratio decreases by a factor of 3.2, the upper limit for $\tau_{\rm La}$ in the mixed layer is about one-third of $\tau_{\rm H2O}$, that is 6.2 yr. Note the anomalous positions of Ce and Eu in the residence times computed in these ways (Table 2b). $\tau_{\rm Ce}$ is shorter and $\tau_{\rm Bu}$ is longer than their position in the REE group might imply.

These estimates for surface ocean residence times for the REE are compatible with aerosol data. From τ and the amount of a rare earth element present in the mixed layer (a) the input flux can be predicted from a/τ . The figure for La is $58\times 10^{-12}\,\mathrm{mol\,cm^{-2}\,yr^{-1}}$ (using τ_{max}). In comparison, typical Al deposition rates $^{33.34}$ of $\sim 5\,\mu\mathrm{g\,cm^{-2}\,yr^{-1}}$ together with La/Al in aerosols which average 14×10^{-4} by weight (using data in ref. 29; La and Al seem to correlate in marine particulates) gives a similar flux of $50\times 10^{-12}\,\mathrm{mol\,cm^{-2}\,yr^{-1}}$. Alternatively, La in the North Atlantic aerosol has been measured $^{24.35}$ at 0.28 ng m $^{-3}$ (using typical Al in aerosols $^{33-35}$ of 150 ng m $^{-3}$ and the above La/Al ratio gives a similar value, 0.21 ng m $^{-3}$). Using a typical depositional velocity of $1\,\mathrm{cm\,s^{-1}}$ gives $64\times 10^{-12}\,\mathrm{mol\,cm^{-2}\,yr^{-1}}$.

980

970

The rapid transport to the deep ocean of the REE scavenged in the surface ocean and their release from the sediment explains the similar REE patterns of deep and surface waters and the link in their enrichments shown in Fig. 2. Thus, the surfacewater enrichments relative to 100 m depth (Fig. 1) of the light REE reflects their preferential removal by scavenging, the sedimented products of which release the REE during early diagenesis leading to stronger deep-water gradients for the light than for the heavy REE. However, we cannot yet rule out in situ regeneration as a source of the REE in deep waters. The Ce anomaly in Fig. 2 might be expected from its redox chemistry in surface seawaters and sediments. In surface waters, Ce released from particles will oxidize and so be removed relative to the 3+ REE. In deep-sea sediments this same reaction means that Ce released from decomposing particles will be less mobile than the 3+ REE (this is observed in terms of the positive Ce anomaly in most oceanic ferromanganese nodules¹) leading to a relatively weaker deep-water gradient for Ce.

The surface and deep sources for the REE suggested here can explain the imbalance in the overall REE budget recognized by Piper¹ and Martin³⁶ who attempted to balance sediment removal with river input only. The residence times with respect to river input (Table 2b—these are minimum values as they are uncorrected for REE removal which occurs in at least some estuaries^{9,36}) are much too long to represent the total input in view of the water mass effects described earlier. A major atmospheric input will redress this balance (Table 2b). Overall, accurate values for τ are difficult to estimate because the atmospheric fluxes into the north-east Atlantic are probably much larger than the oceanic average. However, the atmospheric fluxes may be highly significant. Equally, a benthic flux of the magnitude of the river flux would allow the long riverine residence times to be compatible with the short scavenging residence times. Thus, overall, the REE may reside in the ocean for ~500 yr before being scavenged but are regenerated on average, say, five times before being finally buried and therefore would have residence times with respect to river input of 2,500 yr. The computed values for the overall residence times of the REE (Table 2b) being less than the oceanic mixing time are compatible with the tracing of water masses using REE contents as suggested by the Mediterranean water. In particular, τ for the light REE are short. Thus, the difference between water masses should be more pronounced for the light REE than for the heavy REE, as is observed (Fig. 2). In addition, the value for $\tau_{\rm Nd}$ is consistent with the inter-oceanic differences in the $^{143}{\rm Nd}/^{144}{\rm Nd}$ ratio of seawater $^{7.8,12}$. Although the above described residence times have various shortcomings and uncertainties due to the limited data base and inherent assumptions, their trends clearly reflect our suggested input and removal mechanisms and our basic conclusion that the REE are rapidly cycled in the marine environment.

We thank members of RRS Shackleton cruise 1B/79 and oceanographic and isotopic colleagues at Leeds for their help; and W. & T. Avery Ltd for the use of scales to weigh the ~1,000 kg of seawater. This research was supported by NERC grants GR3/3125 and GR3/4444.

Genome instability in a region of human DNA enriched in Alu repeat sequences

DNA rearrangements involving restriction fragment length polymorphism and variation in copy number were detected in the human genome by blot hybridization with a cloned segment of human DNA initially present in a cluster of Alu repeat sequences. These rearrangements involve both extrachromosomal circular duplex DNAs and integrated sequences, indicating the presence of transposable elements in human cells.

RENATURATION kinetics¹ and genomic library screening² have shown that the human genome contains at least 400,000 copies of the 300-base pair (bp) Alu repeat sequence, the predominant repetitive sequence in man^{3,4}. Members of the Alu repeat family have been proposed to have cellular functions on the basis of various characteristics, including the widely dispersed arrangement of Alu repeats, the conservation of a 40-bp sequence of the Alu repeat in mammalian evolution, the homology of a 14-bp segment with a sequence near the replication origin in several DNA viruses, and the observation that the Alu repeat is represented in transcripts generated by both

RNA polymerase II and III^{5,6}. Thus, a role for Alu repeat sequences in the initiation of DNA replication and nuclear RNA processing has been postulated5,6

The most striking feature of the Alu repeat family is its large numerical representation in the human genome, which suggests that Alu repeat sequences might be involved in genetic rearrangements, a role which could be identified if we consider the human genome to be a dynamic structure. Although most members of the Alu family are scattered throughout the human genome, some may be clustered in certain genomic regions. Such an arrangement would provide a good opportunity to test

Fig. 1 Localization of Alu repeat sequences within the restriction enzyme cleavage map of AH15, AH15 was isolated from a human genomic library as a clone hybridizing to total nick-translated repetitive sequences, grown as previously described2, and the human insert was characterized with respect to the distribution of repetitive sequences. The orientation of the human insert with respect to the left and right arms of the vector was facilitated by knowing the restriction map for Charon 4A24 The localization of Alu repeat sequences was initially derived for the restriction map of AH15, and confirmed for

the restriction map of several segments of λ H15 (subcloned in to pBR322 or pACYC184 and indicated by segments D, A, C and B, respectively) using Southern blot hybridization. with nick-translated Alu repeat inserts from either the clone BLUR 8 or BLUR 2 (ref. 4) as previously described.

the hypothesis that repetitive sequences facilitate genetic rearrangements.

Alu repeat sequences are clustered in regions of the human genome

We searched a human genomic DNA library⁷ for clones containing several Alu repeat sequences, having previously shown that more than 95% of this library contained members of the Alu repeat family² and that in several clones, two or more copies were present (unpublished observation). Clone λ H15, randomly selected as strongly hybridizing to repetitive sequences, was examined in detail. An initial digestion of this clone with several restriction enzymes, followed by Southern blot hybridization with the cloned Alu repeat sequence probes BLUR 2 and BLUR 8 (ref. 4), gave several hybridizing bands, indicating that many Alu repeat family members were present in this 15-kilobase (kb) DNA insert. Double digestion with restriction

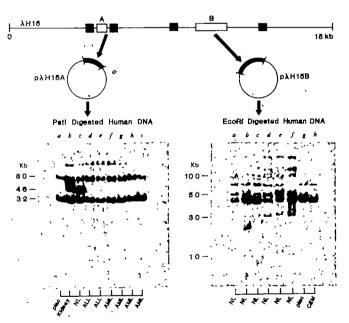

Fig. 2 Experimental design used to investigate DNA rearrangements in tissues of normal and leukaemic individuals. The dark boxes on the human insert of \(\lambda\text{H15}\) represent \(Alu\) repeats sequences flanking the DNA fragments subcloned in pACYC184 (pAH15A) and pBR322 (pAH15B). Subclones were prepared as previously described. Human DNA (10 \(\mu\)g) prepared as described elsewhere \$^{26}\$ was digested with an excess of \$Psil\$ (left side) or \$EcoRI\$ (right side) for 2 h and electrophoresed through 1% agarose gels in 50 mM Tris (pH 8.2), 50 mM boric acid, 10 mM EDTA at 80 V for 6 h. After electrophoresis, the DNA was transferred to nitrocellulose by the method of Southern \$^{25}\$ and the resulting blots were hybridized with 2 \times 10^7\$ c.p.m of labelled pAH15A or pAH15B DNA, prepared by nick translation \$^{27}\$ The hybridization was performed in the presence of 10% dextran sulphate \$^{26}\$ as previously described \$^{26}\$. Filters were exposed for 12 h to X-ray films with intensifier screens. The approximate sizes of DNA in kilobase pairs (kb) in the bands are indicated on the left. plac, Placenta, NL, normal leukocytes; AML, acute myeologenous leukaemia; ALL, acute lymphocytic leukaemia; CEM, a human lymphoblastoid cell line Each lane contains DNA from a different individual.

endonucleases *Eco*RI plus *Bam*HI and *Eco*RI plus *Pst*I showed 7 and 12 bands, respectively, hybridizing to these cloned members of the *Alu* repeat family.

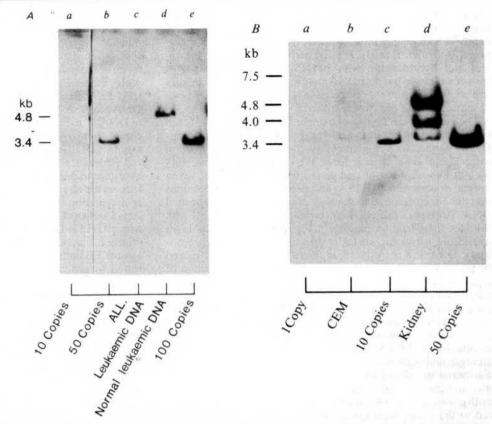

Figure 1 shows the restriction enzyme cleavage map of λ H15, together with the approximate locations of the Alu repeat family members. At least 10 Alu repeat sequences are clustered in this clone, a minimal estimate due to the high degree of divergence among different members of the Alu repeat family⁴. Two observations support this assertion. First, we identified an Alu repeat sequence hybridizing very strongly to BLUR 2 (dark box in Fig. 1) and very weakly to BLUR 8. The sequence divergence between BLUR 8 and BLUR 2 is 24%, thus precluding cross-hybridization in the conditions used. This observation suggests that some members of the Alu repeat family have diverged considerably in the Alu repeat cluster of λH15. Second, in R-loop hybridization between poly(A)⁺ RNA, derived from a human lymphoblastoid line and subclone phH15C (Fig. 1), two additional Alu-like sequences have been detected and positioned with respect to the Alu sequence distribution derived by Southern blot analysis⁶. We may therefore consider the segment of $\lambda H15$ between the first and the fourth EcoRI sites (Fig. 1) as a cluster of Alu repeat sequences.

A role for Alu repeat sequences in genomic rearrangements

The unusual structure of this region provides an opportunity to test the hypothesis that Alu repeat clustering may be involved in genome rearrangements. To investigate this possibility we took advantage of the observation that in λ H15, DNA segments of single copy or very low repetition frequency are flanked on both sides by Alu repeats. Subclones of two of these regions (A and B in Fig. 1) were constructed for use as hybridization probes to detect restriction fragment length polymorphisms (RFLPs) in the genomic region in which the human insert of λH15 is localized. If DNA rearrangements occur in this region at a relatively high frequency, they should be detectable by RFLP analysis. We therefore used cleavage with restriction enzymes and blot hybridization experiments to examine the DNA from tissues of healthy individuals and patients with neoplastic haematological diseases, and found substantial polymorphism with DNA from tissues of healthy individuals using both A and B region probes (Fig. 2). Digestion of several of the DNA samples with other restriction enzymes also revealed patterns of polymorphism. Furthermore, we found that the intensity of one hybridizing band differed markedly among DNAs derived from leukocytes of a normal donor (Fig. 2, lane c, left side) and DNA derived from leukaemic leukocytes (Fig. 2, lanes d-i). These results indicate both variation in the number of hybridizing sequences (copy number) and multiple forms revealed by RFLP of the sequence in human DNA that hybridizes to pλH15A.

Using a gene copy number reconstitution experiment, we determined and compared the number of sequences hybridizing to $p\lambda H15A$ in DNAs derived from leukocytes of a patient with acute lymphocytic leukaemia and a normal individual. The method used has sufficient sensitivity and reproducibility to

Fig. 3 A, determination of the number of human genomic DNA sequences complementary to pAH15A. The numof sequences hybridizing to pλH15A was determined as follows: 5 μg of DNA derived from leukaemic lymphocytes of a patient with acute lymphocytic leukaemia (ALL) (lane c) and from peripheral white blood cells of a normal individual (lane d) digested with BamHI and electrophoresed on a 1% agarose gel with various amounts of BamHI-digested AH15 DNA from which pAH15A was derived. The copy number reference, BamHI-digested AH15, was applied in amounts corresponding to 10, 50 and 100 copies per haploid genome in 5 ug of human DNA (lanes a, b and e respectively). These lanes also contained 5 µg of EcoRI-digested chicken DNA used as carrier. Assuming a human haploid genome size of 3×10^9 bp, the 45-kb λH15 constitutes 1.53×10⁻⁵ of the human haploid genome. Therefore, the amount of AH15 in 5 µg of human DNA, if present at one copy per haploid genome, is $7.6\times10^{-5}\,\mu g$. To apply 10, 50 and 100 copies, 4.5 μg of $\lambda H15$ DNA were digested with BamHI, and the reaction was stopped by adding onefifth volume of a solution containing 50% glycerol, 1% SDS and 0.5% bromophenol blue. Appropriate dilutions were made from this solution. B, number of genomic sequences complementary to pλH15A in DNA of a human lymphoblastoid cell line (CEM) and normal kidney. DNA isolated from

CEM cells and kidney was electrophoresed with 1, 10 and 50 copies of BamHI-digested λ H15 DNA used as an internal standard, and then blot-hybridized to p λ H15A as described earlier. Densitometric scans of the autoradiograms demonstrate that the band at 3.4 kb hybridizing to p λ H15A in CEM cells corresponds to three copies in CEM cells and to approximately six copies in kidney tissue.

give reliable estimates of gene copy numbers 8,9,10 . Titration experiments (Fig. 3A) show that more than 50 copies of sequences hybridizing to $p\lambda H15A$ are present in the leukocytes of the normal individual, compared with less than 5 copies in leukaemic leukocytes. In all the patients with acute leukaemia so far examined (10 cases) we found less than five copies of $p\lambda H15A$ -hybridizing sequences. In contrast, of six patients with chronic myelogenous leukaemia examined, four showed an autoradiographic density comparable with that of healthy individuals, whereas two had copy numbers comparable with that found in acute lymphocytic leukaemia.

The number of sequences hybridizing to pλH15A in DNA derived from leukocytes of normal donors was rather variable but was usually more than 50 copies per haploid genome equivalent. In control experiments, the DNAs derived from normal and leukaemic leukocytes were hybridized with a recombinant plasmid containing the coding region of the human placental lactogen (HPL) gene, present in three to four copies per haploid genome ¹⁰, and equal intensities of hybridizing bands were observed in both DNA groups. We can therefore exclude variations in hybridization efficiency as an explanation of the differences in copy number observed using the pλH15A DNA as probe.

Figure 3B shows an additional example of variations in copy number of sequences hybridizing with p λ H15A. A gene copy number reconstitution experiment reveals that in DNA derived from either a normal kidney tissue or a human lymphoblastoid cell line, a meaningful variation exists in the content of sequences hybridizing to p λ H15A. The bands at 4.8 and 4.0 kb observed in kidney DNA (Fig. 3B, lane d) are not detectable at all in CEM DNA (Fig. 3B, lane b). The only band in common with these DNAs has a size of 3.4 kb and is present at three copies in the lymphoblastoid cell line and six copies in the kidney tissue per haploid genome. The 3.4-kb band, common to the human DNAs shown in Fig. 3, corresponds to the region of clone λ H15 between the BamHI sites at 1.8 and 5.2 kb shown in Fig. 1. We therefore identified variations in copy

number of a specific genomic sequence of human DNA and the results described below indicate that some of the hybridizing bands correspond to circular extrachromosomal molecules.

DNA rearrangements exist in different tissues of the same individuals

Having found variations in copy number and RFLPs in this region of the genome, we next investigated whether different forms of the hybridizing sequence occurred within different tissues of the same individual. A surprising result was that when DNA isolated from a 22-yr old woman who had died of acute lymphocytic leukaemia was digested with EcoRI and hybridized with p\u00bbH15A (Fig. 4A), both RFLPs and a marked difference in the copy number of sequences hybridizing to phH15A were detected among DNAs derived from liver, lung, brain and other organs. Some caution is necessary in interpreting the observed pattern of RFLP because this patient had received combination chemotherapy of doxorubicin, vincristine, cytosine arabinoside and prednisone for 4 days. Nevertheless, we observed RFLPs in these tissues following digestion with EcoRI, BamHI and HindIII which further indicated that tissue-related DNA rearrangements had occurred. A gene copy number reconstitution experiment showed that more than 50 copies of a DNA sequence hybridizing to pAH15A are present in lung and brain tissues, whereas less than 10 copies are present in spleen and kidney tissue (data now shown). Finally, RFLP was also detected in the DNA derived from different organs of a 40-yr old female who had died of melanoma (Fig. 4B), again indicating a frequent occurrence of tissue-related sequence rearrangement using the p\u00e4H15A probe.

Certain sequences hybridizing to p\(\text{H15A} \) occur as extrachromosomal molecules

Variations in the copy number of sequences hybridizing to pλH15A may indicate that these sequences occur in extra-

chromosomal form and are differentially amplified in different tissues or physiological states. Initially, we observed a major band \sim 4.8 kb long in most of the DNAs examined after digestion with EcoRI, BamHI, HindIII and Bg/II (data now shown) and blot hybridization with $p\lambda H15A$. Digestion with PsII revealed a single band of DNA that was \sim 150–200 bp smaller and probably represents cleavage in a single region where two or more PsII sites are closely spaced.

The very unusual finding of a single 4.8-kb fragment for each of the restriction enzymes again suggested that molecules containing sequences complementary to phH15A may exist in extrachromosomal circular form. We examined this possibility by blot hybridization of undigested leukocyte DNA of seven normal donors with phH15A, and detected bands in positions that did not correspond to the bulk of undigested chromosomal DNA. (Compare the ethidium bromide staining pattern with the blot hybridization pattern in Fig. 5A.) The predominant hybridizing bands migrate faster than the bulk of linear chromosomal DNA and correspond to closed circular (A) and nicked circular (B) forms of duplex DNA. A lower concentration of linear duplex DNA of this molecular weight is detected as a faint band migrating slightly faster than nicked circular DNA (labelled 4.8 kb in Fig. 5A, B). These three hybridizing bands occupy relative positions in the gel that would correspond to the positions of nicked circular, linear and covalently closed circular forms of 4.8-kb duplex DNA in similar conditions (ionic strength and voltage gradient) of agarose gel electrophoresis¹ Furthermore, when leukocyte DNA from a normal individual was subjected to a time course digestion with BamHI (Fig. 5B). both closed circular (A) and nicked circular forms were converted to the linear duplex form (labelled 4.8 kb). Note that the nicked circular and linear duplex forms of this DNA species are in low concentration in the undigested sample (Fig. 5B, first lane from the right).

Additional discrete bands of DNA hybridizing with p\(\text{H15A}\) were detected (Fig. 5A). One of them seems to be at an intermediate position between the closed circular and nicked circular forms of the predominant bands of hybridizing DNA, while the remaining bands seem to migrate more slowly than the nicked circular form of the predominant species (bands above B). These additional bands may represent closed circular, linear and nicked circular duplex forms, respectively, of at least

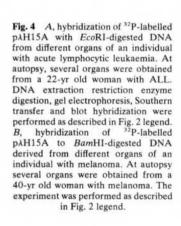

two other species of extrachromosomal DNA that contain sequences complementary to $p\lambda H15A$ but that are present at much lower copy numbers. Perhaps one, but not both, of these species represents a circular oligomer, possibly a circular dimer form, of the predominant species (A and B in Fig. 5A). Furthermore, the time course of digestion of these DNAs with BamHI (Fig. 5B) converts all but one of the higher molecular weight DNA bands to 4.8-kb linear duplex DNA. This remaining band of DNA (C in Fig. 5B), therefore, must represent one additional closed circular DNA species containing sequences complementary to $p\lambda H15A$.

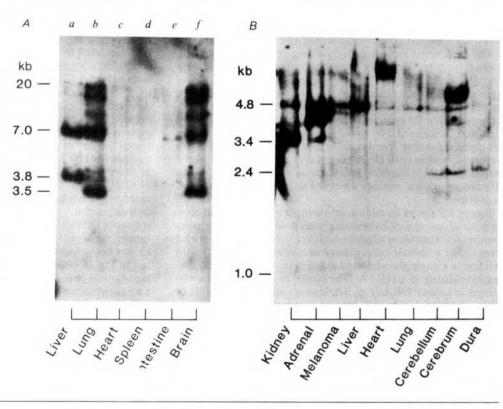

To visualize circular molecules containing sequences that hybridize to $p\lambda H15A$, the undigested chromosomal DNA from leukocytes of a normal individual was fractionated by velocity sedimentation through a sucrose gradient. Fractions were collected and an aliquot of each fraction was blotted and hybridized with $p\lambda H15A$ DNA. One fraction enriched in nicked circular molecules hybridizing to $p\lambda H15A$ was extensively dialysed against TE buffer (10 mM Tris, 1 mM EDTA, pH 8.0), concentrated to a final volume of 50 μ l and examined by electron microscopy using the aqueous Kleinschmidt technique¹².

As Fig. 5C shows, very low frequencies of circular duplex molecules were detected. Of 44 circular duplex molecules examined in this random sampling, 27% comprised a relatively uniform size class (upper row in Fig. 5C), with an average length of 4.71 ± 0.25 kb. A second, smaller homogeneous species was also detected (59% of all molecules), having an average length of 1.77 ± 0.35 kb. The remainder of circular duplex molecules appeared to be heterogeneous in size, with lengths ranging over 0.9-8.3 kb (lower row in Fig. 5C). The finding of a class of circular duplex molecules with a length of 4.7 kb is expected based on the results of blot hybridization experiments with pAH15, which had indicated the existence of a 4.8-kb circular duplex molecule. Supercoiled molecules (not shown) were detected in a faster sedimenting fraction of the sucrose gradient using the formamide modification¹² of the Kleinschmidt technique for electron microscopy.

Discussion

It is remarkable that Alu repeat sequences can exist in a clustered arrangement in the human genome, as revealed by the detailed analyses of the recombinant clone $\lambda H15$. The

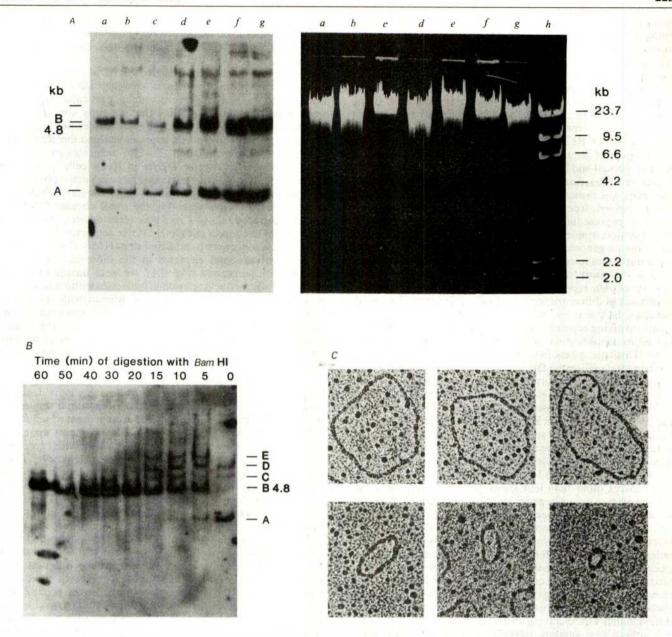

Fig. 5 A, hybridization of ³²P-labelled pλH15A to undigested DNA derived from leukocytes of normal donors. Undigested DNA (5 μg) from seven normal donors was electrophoresed through 1% agarose gels for ~15 h at 40 V. Southern transfer and blot hybridization were performed as described earlier. Hybridization of ³²P-labelled 0.8-kb human insert, purified by two cycles of gel electrophoresis, gave the same bands and relative intensities as blotting with the entire plasmid. B, time course of BamHI digestion of normal leukocyte DNA and hybridization with ³²P-labelled pλH15A. DNA (40 μg) was digested with BamHI at 1 U per μg and 5-μg aliquots were removed at different times. Gel electrophoresis, Southern transfer and blot hybridization with pλH15A were performed as described previously. C, electron micrographs of nicked circular duplex DNAs detected at very low frequency in aqueous Kleinschmidt spreads of nuclear DNA. Undigested DNA (100 μg) from leukocytes of a normal donor was applied to a 10-40% sucrose gradient buffered with 1 mM NaCl, 10 mM Tris-HCl pH 8.0 and 10 mM EDTA, and centrifuged in a VTi 50 rotor at 50,000 r.p.m. for 3 h. Thirty-six fractions of 1.1 ml each were collected and 100 μl of each fraction were electrophoresed in a 1% agarose gel, transferred to a nitrocellulose filter and hybridized with pλH15A as described earlier. The fraction enriched in molecules hybridizing to pλH15A was dialysed extensively against TE buffer, concentrated to a final volume of 50 μl and spread for electron microscopy using the aqueous Kleinschmidt technique 12. The molecules presented in the upper row have an apparent homogeneous length of 4.7 kb and represent ~27% of all circular duplexes detected. Other circular duplexes detected were smaller and heterogeneous in size, as shown in the lower row of micrographs, except for one species having an average length of 1.77±0.35 kb. Length measurements were made relative to the bacteriophage PM2 DNA with a length of 10,260 bp. Scale bar, 1 μm.

clustered arrangement of Alu repeat sequences in $\lambda H15$ may also be common to other regions of the human genome. We have screened the human genomic library with $p\lambda H15A$, which contains a subcloned fragment of $\lambda H15$, to detect DNA regions contiguous with the segment known as H15. Thus far, we have detected nine clones and have characterized five of them in detail. We observed that Alu repeat sequences are abundant in all five clones (T. Somasundaram $et\ al.$, unpublished) which reveals the existence of blocks of Alu sequences in the human genome. This fact is particularly intriguing with regard to the mechanism by which the pattern of interspersion observed for the bulk of Alu sequences is generated.

Sequence analysis showed that the Alu family sequence has

a dimeric structure with a duplication of a region conserved in mammalian evolution 13 . This region, 40 nucleotides long, is present once in the B1 family 14 of repetitive sequences in mouse, which is analogous to the Alu family in man. This internal duplication could have arisen if the initial expansion of Alu sequences occurred in a clustered arrangement like that presented here. We may then visualize the pattern of interspersion of Alu repeat family members as arising from the sequential excision of Alu sequences and their subsequent insertion elsewhere in the genome by mechanisms involving nonhomologous or parahomologous recombination as proposed by Anderson et al. 15 . The pattern of interspersion may have been fixed in evolution, with certain Alu repeat members having been

recruited for specific cellular functions, for example, in the initiation of DNA replication⁵ and as promoter sites for RNA polymerase III^{5,16}.

The discovery of a clustered arrangement of Alu repeat sequences provided an opportunity to explore the general question of sequence rearrangements in the human genome, especially those that may involve Alu repeat sequences. Using sequences from λ H15 DNA, we have detected two distinct aspects of DNA rearrangement involving either differential copy number or RFLPs. There were significant variations in copy number of sequences hybridizing to $p\lambda$ H15A among and between normal and leukaemic individuals. Furthermore, some of this variation could be tissue related, as the same set of sequences was present at different concentrations in different tissues derived from a single individual (Fig. 4A). Thus, sequences represented in the fragments hybridizing to $p\lambda$ H15A are not subject to selective pressures that would fix their number in the human genome.

It is important to emphasize that the 0.8-kb EcoRI fragment, which is the insert fragment in p λ H15A, is itself embedded in a cluster of Alu repeat sequences in the human genome. The occurrence of differential copy number of this sequence could, therefore, be due to the increased frequency of recombination events involving repetitive sequences as proposed by Smith¹⁷ as well as amplification of extrachromosomal circular DNA forms. This latter phenomenon was clearly detected.

When total undigested DNA was electrophoresed and probed with $p\lambda H15A$, we were surprised to find three hybridizing bands that resembled the gel electrophoretic separation of nicked circular, linear and closed-circular duplex forms of DNA (Fig. 5A). Circular duplex DNAs were also detected by electron microscopy after velocity sedimentation of total DNA, although there were two major species with lengths of ~4.7 and 1.8 kb respectively. Circular molecules with lengths other than 4.8 kb and hybridizing to p\(\text{H15A}\) were detected in DNAs derived from sources other than leukocytes. A human skin fibroblast cell line after serial passage for eight generations was found to contain an additional species ~7.5 kb long. The DNAs from liver, lung and brain tissues of one individual (Fig. 4A) all contained extrachromosomal sequences present as circular molecules with sizes different from the predominant circular species detected in normal leukocytes. In particular, electron microscopic examination of the covalently closed circular DNA from lung tissue using propidium diiodide-CsCl density gradient centrifugation revealed a major population (~60%) of the circular DNAs having an average length of 3.4 ± 0.2 kb. In Southern blot analysis, p\u00e4H15A hybridized to this closed circular DNA population after EcoRI digestion and revealed one major band at 3.5 kb, essentially the same as identified by electron microscopy (B.C. et al., unpublished). The DNA from kidney tissue of another individual contained additional hybridizing sequences corresponding to 4.0-kb circular duplex molecules (B.C. et al., unpublished). These variations in size could reflect different genome rearrangements in formation of these circular molecules and may possibly involve duplications or deletions of Alu repeat sequences.

Blot hybridization of undigested leukocyte DNA with a cloned Alu repeat sequence, BLUR 8, or human repetitive DNA revealed the presence of Alu repeat sequences in the leukocyte 4.8-kb circular DNA (B.C. et al., unpublished). In this case, we detected several discrete bands, one of which represented very low molecular weight DNA in the size range corresponding to the length of the Alu repeat sequence. This observation may indicate that Alu repeat sequences themselves occur as small circular duplex DNAs.

Small polydisperse circular DNAs have also been reported to occur at different concentrations in different organs of chicken embryos as well as in the chicken bursa at various stages of development¹⁸. It is possible that the difference in copy number of circular DNAs detected in the leukocyte DNA of normal and leukaemic individuals could reflect the different stages of differentiation of the leukocyte populations. Small

polydisperse circular DNAs were first described for HeLa cells but were found to be quite heterogeneous in size, with a mean length of 0.32 µm (refs 19, 20). Interestingly, the small polydisperse circular DNAs in HeLa cells were shown to be of cytoplasmic but not mitochondrial origin²⁰. It is plausible that low concentrations of small polydisperse circular DNAs exist in the nucleus and, in the tissues we examined, particular size classes were selectively amplified. Note that the copy number of the 4.8-kb circular DNA we describe (~50 copies per leukocyte haploid genome) corresponds approximately to the copy number of the entire population (50–200 molecules per cell) of small polydisperse circular DNAs in HeLa cells²⁰, implying selective amplification of a particular size class in the population of polydisperse DNA examined. The circular DNAs we detected more closely resemble the small circular DNAs in nuclei of cultured cells of *Drosophila melanogaster*, which have been shown to contain middle-repetitive sequences²¹.

Although sequences hybridizing to phH15A DNA occurred as extrachromosomal elements in the different tissues of a woman with leukaemia (Fig. 4A), we were unable to detect, unequivocally, extrachromosomal molecules without restriction enzyme digestion in tissues from a woman with melanoma (Fig. 4B). However, DNA from tissues of this individual contained a 4.8-kb hybridizing band (Fig. 4B) which in other cases corresponded to extrachromosomal DNA. The other discrete bands in the different tissues of this individual may indeed represent RFLP of chromosomal sequences, Therefore, the occurrence of H15A hybridizing restriction fragments of different lengths in different tissues of the same individual may involve either chromosomal or extrachromosomal sequences. Furthermore, the copy numbers and arrangement of sequences hybridizing to phH15A as chromosomal segments appear to differ in other tissues. In this regard, a 3.4-kb BamHI fragment (Fig. 3A, B) is present in three copies in leukocyte DNA whereas at least six copies are present in kidney tissue (Fig. 3B), indicating that a duplication involving this segment has occurred to different extents in the two cell types. The occurrence of such variation in copy number is further confirmed by the finding that nine clones contain sequences homologous to phH15A in a human genomic DNA library established from fetal liver tissue⁷. Five of these clones were analysed and shown to represent segments of the human genome different from H15. Furthermore, in the liver tissue from which the library was established, the arrangement of sequences probed with p\lambda H15A differs from that found in leukocyte DNA. This conclusion is drawn from the observation that possibly two chromosomal fragments in PstI-digested leukocyte DNA hybridize with pλH15A (Fig. 2) rather than five or more as expected.

These combined studies indicate that polymorphisms and variation in copy number of chromosomal and extrachromosomal DNA sequences hybridizing with pλH15A reflect the presence of transposable elements in human cells. The recent observation that *copia*, the well known transposable element in *Drosophila*, exists in extrachromosomal form in cultured cells²² adds significance to the present results. In general, the human genome seems to be a dynamic structure in which variations can be introduced by sequence rearrangement, certain of which can lead to the formation of circular duplex DNA molecules. This genetic plasticity is quite characteristic of transposable elements, and the consequent genome alterations are relevant to evolutionary changes, while the DNA rearrangements may be involved in human cancer²³.

We thank Dr R. Shmookler Reis for many helpful suggestions during this work, Nancy Yen and Debbie Brock for technical assistance, T. Maniatis for the human genomic DNA library, P. Deininger and C. Schmid for the Alu repeat plasmids, and Abby Maizel for providing CEM cells. This investigation was supported by NIH grants GM 23965, GM 27774, CA 20124, CA 16672 and CA 16527, and Robert A. Welch Foundation grants G-267 and G-841. H.A.B.-S. was supported by a scholarship from the Consejo Nacional de Ciencia y Tecnología (CONACYT) of the Mexican government.

A new model for white dwarf supernovae

R. Canal, J. Isern & J. Labay

Departmento de Física de la Tierra y del Cosmos, Universidad de Barcelona, Barcelona 7, Spain

We show here that carbon-oxygen white dwarfs in close binary systems are likely progenitors of neutron stars and Type I supernovae (SNI). This conclusion is supported by different effects associated with crystallization of the carbon-oxygen mixture at relatively low temperatures ($T \le 5 \times 10^7$ K) and high densities $(\rho > 5 \times 10^9 \text{ g cm}^{-3})$. In particular, the existence of a pronounced extectic in the phase diagram of carbon-oxygen mixtures induces carbon-oxygen separation, with oxygen settling at the star's centre and carbon being rejected to lowerdensity layers. This not only favours 'quiet' or non-explosive collapse, but it may also induce off-centre ignitions at variable depths. We discuss their possible correspondence with the 'fast' to 'slow' SN I range.

Carbon-oxygen white dwarfs in close binary systems are generally thought to be at the origin of nova outbursts¹ and their significance for SNI explosions has been suggested^{2,3}. Current models of SN I light curves^{4,5} involve explosive carbonoxygen burning with ejection of variable amounts (from 0.5 to $1.0\,M_{\odot}$) of ⁵⁶Ni. This burning is triggered in various ways by mass accretion from the companion in the binary system. Several mechanisms have been proposed: central carbon deflagration for accretion rates in excess of 4×10⁻⁸ M_☉ yr (ref. 6); helium detonation at the base of the accreted layer, for $1.10^{-9} M_{\odot} \text{ yr}^{-1} \le \dot{M} \le 4 \times 10^{-8} M_{\odot} \text{ yr}^{-1}$ (ref. 7); finally, central carbon deflagration or low-depth helium detonation again, for $\dot{M} \leq 1 \times 10^{-9} M_{\odot} \,\mathrm{yr}^{-1}$, the former for white dwarf masses in excess of $1.2 M_{\odot}$, the latter for lower white dwarf masses⁸. All of these hypotheses suggest complete disruption of the white dwarf, with no remnant left and ejection of all of its material, with variable compositions. Also, these models have central temperatures of a few hundred million kelvins and ignite at a central density of about 3×10^9 g cm⁻³.

Our model⁵⁻¹¹ involves white dwarfs which have cooled for

a long time ($t \ge 9 \times 10^8$ yr), so reaching low temperatures ($T \le$ 5×10^7 K) and high central densities ($\rho_c > 5 \times 10^9$ g cm⁻³; this implies a rather high mass: $M \ge 1 M_{\odot}$). Such a situation is likely when the white dwarf's companion star is a low-mass mainsequence star. Then, the detached phase of the system can be very long: $t \ge 10^9$ yr.

The main difference between this and models mentioned earlier is that the carbon-oxygen mixture becomes solid at such temperatures and densities. While carbon ignition in the fluid phase is still an open problem which awaits a two-dimensional

hydrodynamical treatment, solidification introduces important new features.

First, carbon is ignited by pycnonuclear reactions driven by the zero point energy. So, the thermal stability limit is increased to $\rho_0 = 6 \times 10^9$ g cm⁻³. This is still less than the dynamical stability limit, due to electron captures on 16 O, which is ρ_c = 1.92×10¹⁰ g cm⁻³. But an important effect of solidification is to reduce the mechanisms of burning propagation (in the absence of detonation) to conduction alone 12. Because a detonation seems unlikely to form on carbon ignition for densities $\rho \ge 10^7$ g cm⁻³ (ref. 13), solidification thus implies relatively low speeds for burning propagation (~10⁻⁵ times the speed of sound).

To exclude helium detonation in the outer, accreted layers, we limit ourselves to only two accretion regimes: fast accretion

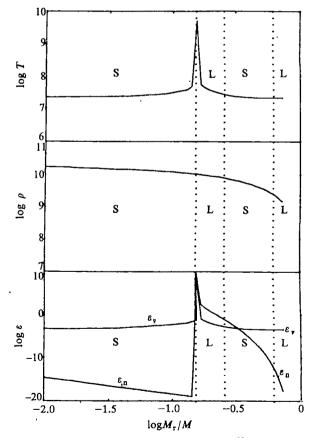

Fig. 1 Stellar structure during the off-centre ¹²C flash. Temperature and density profiles are plotted against stellar mass fraction. Also shown are the energy releases (ε) by the nuclear (fusion) reactions (ε_n) and the e^- captures, together with the thermal neutrino losses (ε_ν) . S and L correspond to the solid and to the melted (Coulomb liquid) zones, respectively.

 $(\dot{M} \ge 10^{-8} M_{\odot} \text{yr}^{-1})$, possibly associated with Roche lobe overflow by the companion, and slow accretion $(\dot{M} \leq 10^{-10} \, M_{\odot} \, \text{yr}^{-1})$, more likely corresponding to accretion from the companion's stellar wind or to decay of the orbit by gravitational radiation.

We have also considered¹² a very fast accretion rate, $\dot{M} \sim$ $10^{-6}\,M_\odot\,\mathrm{yr}^{-1}$ (of the order of the Eddington limit for those stars), and obtained central ¹²C ignition at ρ_c = $1.37 \times 10^{10} \,\mathrm{g \, cm^{-3}}$. Due to the relative slowness of burning propagation in the solid phase, electron captures on the incinerated material overcome the effects of explosive burning and collapse ensues. This study did not include the behaviour of the accreted matter but only its effects in increasing the star's mass and density, and adiabatic gravitational compression. Problems such as the possible formation of an extended red giant envelope¹⁴ or heating of the core by a helium burning shell were not considered. So the real outcome remains unclear and this case serves only to illustrate one of the effects of solidification on pre-supernova evolution. For slower accretion rates those problems may be overcome but ¹²C ignition happens at lower densities $(6 \times 10^9 \text{ g cm}^{-3} \le \rho_o \le 1 \times 10^{10} \text{ g cm}^{-3})$ and electron captures on the incinerated material are also slower. Those cases need further study.

A more important effect of solidification is the possibility of chemical separation. Stevenson¹⁵ has pointed out that the phase diagram of 12C-16O mixtures presents a pronounced eutectic (or temperature minimum in the phase diagram) which corresponds to a composition of 66.8% ¹²C and 33.2% ¹⁶O, both by number. For a 'standard' chemical composition $(X_C = X_O =$ 0.50), the solidification process would undergo the following: (1) 16O 'snowflakes' settling at the centre of the star. (2) The oxygen-depleted fluid is rehomogenized by 'salt finger'-like instabilities. (3) Solid ¹²C begins to form when the fluid composition becomes eutectic. (4) ¹²C crystals, being lighter than the fluid mixture ¹⁶, rise and redissolve higher up. (5) Given enough time, a completely differentiated body is formed.

Note that the cooling process is slowed down by the chemical separation process, as the last involves releasing gravitational potential energy. This effect can be estimated as follows.

The relative change in gravitational potential energy is of the order: $\Delta\Omega/\Omega \sim 10^{-3}$. Typical values for a 1 M_{\odot} star at the beginning of crystallization¹⁷ are: $-\Omega = 4.72 \times 10^{50}$ erg and $L = 10^{-3}$ crystallization¹⁸ are: $-\Omega = 4.72 \times 10^{50}$ erg and $L = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $L = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $L = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $L = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $L = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $L = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $L = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 4.72 \times 10^{-3}$ erg and $-\Omega = 10^{-3}$ crystallization¹⁹ are: $-\Omega = 10^{-3}$ cr $1.6 \times 10^{-3} L_{\odot}$. Thus $t = -\Delta \Omega/L = 2.5 \times 10^9$ yr. This means a non-dramatic increase of the time scale of cooling, which was already $t_{cool} \sim 10^9$ yr. It is appreciable, however, and this indicates that partial differentiation when mass accretion begins should be comparatively frequent.

We have calculated the precollapse and/or presupernova evolution of chemically differentiated carbon-oxygen white dwarfs. Our results show that for complete carbon-oxygen separation and for both slow and fast accretion rates (with the reserves previously pointed out concerning very fast rates), the behaviour of the central layers is: (1) heating of the star's centre by electron captures on 16 O, from $\rho_c = 1.92 \times 10^{10}$ g cm⁻³. (2) ¹⁶O melting and building up of a superadiabatic temperature gradient, with convection being stopped by the μ_e -gradient. (3) Growth of 16 C abundance through 16 O +2 $e^- \rightarrow ^{16}$ C +2 ν_e . (4) ¹⁶C ignition when its abundance reaches ~10% by number. The overpressures in the star's centre are small and cannot start a detonation. Burning propagates outwards by conduction alone (the surrounding layers are still solid). The electron captures on the incinerated material being very fast at those densities, ¹⁶C ignition acts as the triggering mechanism for the collapse. Off-centre ignition of ¹²C is still possible during the hydrodynamic compression of the outer half of the star's mass, but this phase is beyond the scope of the present study.

We have also evolved partially differentiated models, in particular those with a central oxygen core surrounded by an eutectic carbon-oxygen mixture ($\sim 0.25 M_{\odot}$ of ¹⁶O surrounded by $\sim 1.15 M_{\odot}$ of ¹²C-¹⁶O). For fast accretion the behaviour of these models is similar to that of the completely differentiated ones. For slow accretion $(\dot{M} = 10^{-12} M_{\odot} \text{yr}^{-1})$, however, ¹²C

ignition happens just at the base of the carbon-oxygen layers. The structure of this model at the time of carbon flash is shown in Fig. 1. Deflagrative carbon burning may, in this case, lead to the ejection of the carbon-oxygen layers after their incineration. The size of the central oxygen core being variable for different degrees of carbon-oxygen separation (corresponding to different cooling times), our model might account for thermonuclear burning of C-O, incineration and ejection of different amounts of material, in the approximative range of $0.5-1 M_{\odot}$. This would agree with Arnett's explanation of the 'fast' to 'slow' SN I range, which involves ejecting from 0.5 M_☉ of ⁵⁶Ni (in the 'slow' SN I) to 1 M_{\odot} of ⁵⁶Ni (in the 'fast' SN I).

Our model, besides leading to neutron star formation, seems also to be a promising explanation for Type I supernovae. The dynamical phase, of mass ejection and/or collapse of the inner zones, must be further explored to ascertain the exact amounts and the chemical composition of the matter expelled. Were our preliminary results confirmed, a single parameter (the duration of the cooling phase) would explain, within the slow accretion regime, the entire range of 'fast' to 'slow' SN I.

A Compton-cooled feedback mechanism for Cygnus X-1

P. W. Guilbert* & A. C. Fabian

Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK

The spectrum of the X-ray source Cygnus X-1 appears to exhibit two states. The source spends most of its time in the so-called 'low state' in which it is characterized by a power-law spectrum, $N(\varepsilon) \propto \varepsilon^{-\alpha}$, of photon index 1.6 and high-energy cutoff ~ 100 keV (ref. 1). Occasionally it makes a transition to a high state² during which the soft flux (1-3 keV) increases by a factor of a few and the X-ray spectrum changes to an index steeper than 2.5. Most of the interpretation of the spectrum of Cyg X-1 has centred on the comptonization of soft photons by a hot gas in an accretion disk surrounding a black hole^{1,3}. It has been assumed that the hot gas is held at a fixed temperature, despite the obvious high degree of variability observed in the source on time scales ranging from milliseconds to months^{4,5}. We consider here the effect of relaxing this assumption of constant temperature because a Compton-cooled gas, in which the gas temperature drops in response to the comptonization of soft photons, can readily produce a two-state time-averaged spectrum from variations in the soft flux⁶. We speculate on a feedback mechanism that may effectively lock the source in either of the two states.

The slope and high-energy cutoff of the spectrum in the low state indicate, from computations of Compton-cooling gas⁶ that the Thomson depth τ of the gas is ≥ 2 and that the initial

Present address Joint Institute for Laboratory Astrophysics, University of Colorado and National Bureau of Standards, Boulder, Colorado 80309, USA

gas temperature kT is ~100 keV. Page et al.⁷ measured a lag time (in the high state) for the variations in the 3-40 keV flux compared with the 1-3 keV flux of ~7.5 ms. This is characteristic of the shortest time scales seen in the source apart from the ill-defined submillisecond bursts, the significance of which may be in doubt⁵. Using this lag time scale as a rough guide to the photon escape time, t_e , from the hot gas we find

$$t_{\rm e} \simeq \frac{\tau^2}{n_{\rm e}\sigma_{\rm T}c} = \frac{\tau R_{\rm x}}{c} = 7.5 \times 10^{-3} f$$
 s

where n_o is the electron density, R_x is a typical dimension of a hot gas cloud in the source and f is a factor allowing for the uncertainty in cloud geometry. Thus

$$R_{x} = 1.1 \times 10^{8} \left(\frac{2}{\tau}\right) f \quad \text{cm} \tag{1}$$

and

$$n_e = 2.7 \times 10^{16} \left(\frac{\tau}{2}\right)^2 f^{-1} \text{ cm}^{-3}$$
 (2)

Conservation of energy then implies that the maximum X-ray luminosity

$$L_{\text{max}} \simeq n_{\bullet} (3kT) \frac{4\pi}{3} R_{x}^{3} n_{c} t_{e}^{-1}$$

$$= 10^{37} \left(\frac{2}{\tau}\right) n_{c} f \quad \text{erg s}^{-1}$$
(3)

where n_o is the mean number of clouds present at a given time. The actual luminosity is $(t_o/t_{\rm cool})L_{\rm max}$. (The maximum bremsstrahlung luminosity from this region is almost 100 times smaller.) Observations of L in the low state indicate that fn_o is at least a few^{1,2}. The average scattered photon energy is given by

$$\frac{\langle \varepsilon_{x} \rangle}{\varepsilon_{0}} = \frac{\alpha - 1}{2 - \alpha} \left[\left(\frac{kT}{\varepsilon_{0}} \right)^{2 - \alpha} - 1 \right] \left[1 - \left(\frac{\varepsilon_{0}}{kT} \right)^{\alpha - 1} \right]^{-1} \tag{4}$$

which in the low state, where $\alpha \sim 1.6$ and $\varepsilon_0 \sim 0.5$ keV (refs 2, 8), gives $\langle \varepsilon_x \rangle / \varepsilon_0 = 12$. Then because the observed soft and hard luminosities are similar², we see that only $\sim 10\%$ of the soft photons can be scattered in the hot clouds. We have already noted that τ in the clouds >2, so we conclude that most of the soft photons originate in a region physically separate from the hot gas clouds, ruling out any simple coronal model. The cooling time of a cloud⁶

$$t_{\rm cool} \simeq \frac{3\varepsilon_0}{L_{\rm s}} \exp\left(t_{\rm therm}/t_{\rm e}\right) \frac{4\pi}{3} R_{\rm x}^3 n_{\rm e},\tag{5}$$

where the time taken for photons to scatter to $\varepsilon \sim kT$

$$t_{\text{therm}} = \frac{\log\left(\frac{kT}{\varepsilon_0}\right)}{\log\left(1 + \frac{4}{x}\frac{K_3(x)}{K_2(x)}\right)} (n_{\bullet}\sigma_{\text{T}}c)^{-1}$$
 (6)

 $(x = m_{\rm e}c^2/kT, K_3(x))$ and $K_2(x)$ are modified Bessel functions and L_s is the incident soft photon luminosity at ε_0). Now $L_s \sim 10^{36} n_{\rm e}^{-1}$ erg s⁻¹ in the low state, so for $\tau = 2$ we find

$$t_{\rm cool}^1 \simeq 2 \times 10^{-3} n_c f^2$$
 s (7)

The hard spectrum (together with equation (3) which indicates the value of $n_0 f$) implies that $t_{\infty ol}^1 > t_0$ in the low state. Large variations of the X-ray flux observed on time scales of 20–30 ms (ref. 5) indicate that $n_0 f$ cannot much exceed 10, because a large average number of hot clouds would smooth out variations on time scales of a few times t_0 . In the low state therefore, $t_0 < t_{\infty ol}^1 < 3t_0$ as $\tau \ge 2$. The cooling time is inversely proportional to L_1 , which increases in the high state, so that then $t_0 > t_{\infty ool}^1$. This means that the gas cools significantly before many photons are able to scatter far up in energy resulting in a steeper

spectrum⁶. Comptonized bremsstrahlung, from the rapidly cooling hot clouds, may produce a detectable hard tail to the spectrum in this state. Model spectra have been produced using the method given in ref. 9 assuming an initial gas temperature of 100 keV and predict greater X-ray flux above 100 keV than do the constant temperature comptonization spectra from gas at $kT \sim 30$ keV (refs 1, 10). We can obtain good agreement (by eye) over the 3-500 keV range of the HEAO 1 spectrum from a Compton-cooled model.

The time-averaged spectral index of Compton-cooled gas in the low state is independent⁶ of L_{\bullet} provided that $t_{\infty ol} > t_{en}$ although $L_{\star} \propto L_{\bullet}$. L_{\star} can, moreover, change independently of L_{\bullet} if τ , T or n_{c} change. The spectral index is sensitive to the soft flux in the high state, steepening (flattening) as the flux increases (decreases). The Compton-cooling model can be tested by observing the spectral evolution of a luminous burst. If the temperature of the hot gas is fixed, then the X-ray spectrum of the burst will continually harden with time until it assumes its final shape. If the gas cools, on the other hand, the spectrum will only harden until $t \sim t_{\infty ol}$ (or t_{\bullet} , which ever is the larger) and then it will begin to soften again. The minimum time scale for variations of the soft flux is expected to be the dynamical time scale (of the disk) in the region of its emission³

$$P \simeq 0.5 \left(\frac{M_{\star}}{M_{\odot}}\right)^{-1/2} \left(\frac{R}{10^8 \text{ cm}}\right)^{3/2} \text{ s}$$

We envisage a simplified picture of Cyg X-1 in which soft photons cool clouds of hot gas from $kT \sim 100$ keV on time scales of ~10 ms. The published spectra are the time averages from many clouds which may have passed through many heating (by shocks perhaps) and Compton-cooling phases. The system may lock itself in the two states through feedback provided by the X-ray spectrum. We suppose that the soft photon source is cool gas near to the hard X ray-emitting clouds. The soft photon flux determines t_{cool} and thus the slope of the spectrum of the X rays incident on the cool gas. When $\alpha > 2$ (the low state) the highest-energy photons (~100 keV) dominate this effect which is predominantly heating. This may reduce the soft flux and maintain $t_{cool} > t_o$ and thus $\alpha > 2$. When $\alpha > 2$ (the high state) the lowest-energy photons (>1 keV) dominate and may even have a cooling effect on the soft photon-emitting gas. This may provoke the production of soft photons and maintain $t_{\rm cool} > t_{\rm c}$ and thus $\alpha > 2$. This situation therefore leads to the source latching into either state according to the initial value

To be more specific, we envisage this process occurring in an accretion disk where the X ray-emitting clouds are associated with a thickening due to the local heating exceeding the local cooling rate (the 'thermal instability'3,11). The X rays add a term to either the local heating or cooling rate depending on the spectral slope, thereby increasing or decreasing the size of the X ray-emitting region at the expense of the cool one. The importance of the X-radiation can be estimated by considering a boundary region at R_u of incremental radius h equal to the local half thickness of the cool disk. The flux of X-radiation incident on the boundary is $L_x h/R_u$, which is comparable with the local rate of dissipation of gravitational energy $GMMh/R_u^2$. This last quantity is $L_{\bullet}^{T}h/R_{u}$ or $L_{x}h/R_{u}$, depending on whether the cool region is at a larger or smaller radius than the X ray-emitting region. L_s^T is the total soft X-ray luminosity ($\sim L_x$ in the low state). An increase in M, and thus of L_{\bullet} , of sufficient magnitude to change t_{cool}/t_e , could change R_n and thereby force the system to change its state and remain there until an opposite change occurs. The inferred large value of L_{\bullet}^{T} in Cyg X-1 $(L_s^T > L_x)$ suggests, for an accretion model, that the luminous soft flux originates from an area at a smaller radius than the X-ray region (which requires some special geometry in order that only 10% of the photons are intercepted by the hot gassee Fig. 2 in ref. 12 which illustrates this general configuration; the details are different). This would mean that soft (<2 keV) X-ray measurements of Cyg X-1 are the most direct probes of

the black hole, and that the soft X rays probably control the shortest time-scale variability. Possible alternative solutions are that \dot{M} decreases with radius due to a wind, or that the efficiency is low in the hot region because the black hole swallows much of the kinetic energy with the matter. Clearly our model requires a significant perturbation to drive it from one state to the other. The size of the necessary perturbation required to drive the system from low to high (high to low) will depend on $t_{\rm cool}^{\rm h}/t_{\rm e}(t_{\rm cool}^{\rm l}/t_{\rm e})$. The longer time spent in the low state may simply reflect the greater stability of that state to changes in the soft flux.

We conclude that, in the framework of a Compton-cooled plasma, the flat hard X-ray spectrum and rapid variability observed in the low state of Cyg X-1 imply that the Comptoncooling time, t_{cool} , just exceeds the photon escape time from the hot clouds, t_c . Feedback through the following loop then maintains that low state: $\alpha < 2 \Rightarrow$ emission from hot gas heats surrounding cool gas $\Rightarrow L_s$ decreases $\Rightarrow t_{cool}$ increases $\Rightarrow t_{cool} >$ $t_e \Rightarrow \alpha < 2$. A substantial increase in L_s , perhaps due to a temporary change in \dot{M} , may then cause a change to the high-state loop: $\alpha > 2 \Rightarrow$ emission from hot gas cools cool gas $\Rightarrow L_s$ increases $\Rightarrow t_{cool} < t_e \Rightarrow \alpha > 2$.

Alkylation of lead (II) salts to tetraalkyllead in aqueous solution

L. J. Snyder

Ethyl Corporation, R & D Laboratory, Baton Rouge, Louisiana 70801, USA

J. M. Bentz

Ethyl Corporation, Research Laboratory, Detroit, Michigan, USA

It was recently reported by Ahmad et al.1 that lead (II) salts react with alkyl iodides in aqueous solution to produce tetraalkyllead compounds. They stated this reaction would have serious environmental consequences for water quality and for the well-being of aquatic biota. The experiments were carried out in a small (250 ml) flask nearly filled with an aqueous lead (II) acetate solution (210 ml) and sealed with an aluminium foil wrapped stopper. We have now repeated the experiment and report that tetramethyllead (TML) is not formed by direct reaction of lead (II) salts with methyl iodide in an aqueous system, but comes from a secondary reaction of metallic lead with methyl iodide2.3. Apparently, Ahmad et al.1 inadvertently contacted the aluminium foil-wrapped stopper with a small quantity of lead (II) acetate solution to produce finely divided metallic lead which reacted with methyl iodide to produce TML. The reduction of lead (II) salts to metallic lead in both acid and alkaline solutions by aluminium and other metals has been reported previously⁴. When the reactions described by Ahmad et al.1 were carried out in the absence and presence of aluminium, TML formed in those tests in which lead (II) acetate solution contacted aluminium but not when aluminium was absent. Our results indicate that methylation of lead (II) acetate does not occur in the environment to form tetraalkyllead compounds which would be deleterious to water quality.

We have repeated the alkylation experiments described by Ahmad et al. by reacting lead (II) acetate with methyl iodide in aqueous solutions adjusted to pH 5-6 and pH 13 respectively. The experiments carried out in alkaline solution at pH 13 are reported in Table 1. Alkylation runs 1 and 2 were carried out as described by Ahmad et al. by dissolving 1.0 mmol of lead (II) acetate in 200 ml of deionized water in a 250 ml filtration flask fitted with an aluminium foil-wrapped stopper. Methyl iodide (0.1 ml) was added and the flask was sealed and stored in a closed cabinet. After 5 days the mixture (vapour space and aqueous solution) was extracted with n-heptane. The TML content of n-heptane was measured by a colorimetric dithizone method⁵ modified to measure the absorbance of dialkyllead dithizonate in a small volume (0.9 ml) of chloroformdithizone solution at 485 nm wavelength. Results from the first two experiments (Table 1) using an independent method of analysis agreed well with those reported by Ahmad et al. 1. In the next three runs, contact between the aluminium foil-wrapped stopper and the lead (II) acetate solution was controlled. The foil in runs 3 and 4 was deliberately and completely wetted with lead (II) acetate solution (pH 13) at the start and occasionally during the experiment. Special precautions were taken to avoid contact between the foil-wrapped stopper and lead (II) acetate solution in run 5. The results of these runs demonstrate that TML is produced only if the aluminium foil-wrapped stopper contracts the lead (II) acetate solution. Significantly more TML was formed when the aluminium foil was intentionally wetted than in runs 1 and 2 where there was minimal and unintentional contact between lead (II) acetate solution and aluminium foil.

As further proof that there is no reaction between lead (II) acetate and methyl iodide in aqueous solution (pH 13) to produce TML, we increased the sensitivity of the colorimetric dithizone method by a factor of 10 by scaling up proportionally the quantities of lead (II) acetate, methyl iodide, aqueous solution and glassware used in the alkylation reaction. The reactants and solvent were maintained in the ratios used by Ahmad et al. 1. Repeat experiments were carried out in the absence of aluminium with the bottles sealed with screw caps lined with Teflon gaskets. No detectable quantities of TML (<0.01 p.p.b. as Pb) were produced from these tests (runs 6-10) carried out over 5-50 days.

Methylation tests were then carried out at pH 5-6. Aluminium was added directly to the lead (II) acetate solution in

Table 1 Reaction of lead ((II) acetate with methyl iodide in aqueous solution (pH 13)

Run no.	Reaction period (days)	Experimental conditions	TML found (p.p.b. Pb in water)
1	5	a	1.2
2	6	a	1.5
3	5	b	8.5
4	5	ь	10.2
5	5	c	< 0.1
6	5	d	< 0.01
7	5	d	< 0.01
8	10	d	<
9	18	d	< 0.01
10	50	d	< 0.01

a, Aluminium foil present and methylation test carried out as described by Ahmad et al. 1. b, Aluminium foil deliberately wetted with lead (II) acetate solution (pH 13). c, Aluminium foil present but kept free of lead (II) acetate solution (pH 13). d, Absence of aluminium foil; the methylation experiments were scaled up proportionally to provide increased analytical sensitivity. In all cases, temperature was 23 ± 2 °C. Note that Ahmad et al. found 370.5 ng of TML in a flask containing 200 ml of aqueous solution, which is equivalent to a 1.44 p.p.b. calculated as Pb in water.

Table 2 Reaction of metallic lead with methyl iodide in aqueous solution

Run no.	Reaction period (days)	рН	TML found (p.p.b. Pb in water)
1	7	13	744.0
2	6	13	2,375.0
3	5	Initially 5.5	< 0.01
4	9	Initially 5.5	< 0.01

Sample no. 2 contained 10 g of freshly sliced metallic lead while sample 1 contained 5 g of lead. However, the weight of lead is less important than the surface area of the freshly sliced lead. Samples 3 and 4 contained 8 g of freshly sliced lead. All tests contained 1,140 p.p.b. of methyl iodide in water. Temperature 23 ± 2 °C.

some experiments and omitted in others. The head space in the 250 ml flask was analysed by a gas chromatography/atomic absorption spectrometry procedure essentially as described in ref. 6 and having the same sensitivity as the method of Ahmad et al.¹. In these experiments, TML was detected only when the aluminium was contacted with lead (II) acetate solution.

That metallic lead is produced from the reduction of lead (II) acetate was confirmed by adding aluminium foil to (1) lead (II) acetate dissolved in distilled water (pH 5.5) and (2) lead (II) acetate solution adjusted to pH 13 with NaOH. The metallic lead produced was identified by scanning electron microscopy/energy-dispersive X-ray spectrometry. The reduction at pH 5.5 is much slower than at pH 13, which may explain why Ahmad et al. found significantly smaller quantities of TML in slightly acid solutions.

Although the reaction of metallic lead with methyl iodide has been reported previously^{2,3}, we have demonstrated here that this reaction depends on the extent and character of the lead surface and the specific conditions in which the test is carried out. When we added freshly sliced metallic lead to a NaOH solution (pH 13) containing methyl iodide, TML was readily produced (Table 2). On the other hand, no TML was detected when freshly sliced lead was added to distilled water (pH 5.5) containing methyl iodide and the mixture allowed to stand in the dark and in a completely sedentary condition for 5-9 days (Table 2). In the latter case a rapid growth of insoluble hydrated lead oxides formed on the surface of the metallic lead, presumably inhibiting the alkylation reactions. In the presence of surface waters, metallic lead would be expected to react with other anions, such as sulphides, carbonates and phosphates, to form water-insoluble lead compounds adhering to the surface of the metal that would reduce or eliminate any alkylation of metallic lead with alkyl iodides, even if they were present in very high concentrations. Caution must be exercised against predicting whether metallic lead may be methylated in the environment by extrapolating information from laboratory experiments, especially as metallic lead and methyl iodide are chemically unstable in water.

When Jarvie and Whitmore⁷ repeated the lead (II) salt-methyl iodide reactions described by Ahmad et al.¹, no TML was observed when the reactions were carried out in the presence and in the absence of aluminium foil-wrapped stoppers. These authors attempted to explain their negative results on the basis of possible minor differences in temperature, time, pH, light effects, for example, from the conditions used by Ahmad et al.¹. However, we believe the correct explanation is that none of the aqueous lead acetate solution inadvertently contacted the aluminium foil-wrapped stoppers.

Aerosols of high chlorine concentration transported into central and eastern United States

R. W. Shaw Jr & F. S. Binkowski

Environmental Sciences Research Laboratory, US Environmental Protection Agency, Research Triangle Park, North Carolina 27711, USA

W. J. Courtney

Northrop Services, Inc., Research Triangle Park, North Carolina 27709, USA

During 18-21 December 1980 a remarkable change occurred in the composition of the aerosol over a broad region of the central and eastern United States: the weight per cent of chlorine present in small aerosol particles increased by nearly two orders of magnitude. We report here an analysis of the aerosol composition and meteorology during the period of change which suggests that this increase was the result not of a pollution episode, but of a massive intrusion of very clean maritime air from the northern Pacific into a region extending at least from Wisconsin southwards to Kansas and Missouri and eastwards to Ohio.

We obtained elemental composition data for the event from X-ray fluorescence analysis of aerosols collected using virtual impactor (dichotomous) samplers. These samplers separate aerosols into 'fine' and 'coarse' fractions (<2.5 and 2.5-15 µm in aerodynamic diameter, respectively). Particles in the fine aerosol fraction have settling velocities in still air of ≤10⁻² cm s⁻¹; consequently they may remain suspended for days or longer and may be transported long distances by largescale atmospheric motion. The fractions were collected on Teflon membrane filters over 24-h intervals starting at midnight. Locations where aerosol samplers were operating during the period of interest and for which we have aerosol elemental composition data are three rural sites (in Kentucky, Indiana and Ohio); Portage, Wisconsin; Topeka, Kansas; and St Louis, Missouri¹. The rural sites were chosen as being representative of regional air quality and to avoid local emission sources as far as possible; these sites were located at 37°41' N, 88°01' W; 39°28' N, 84°56' W; and 40°36' N, 82°19' W. Aerosols were collected on odd-numbered days in Portage and Topeka and daily elsewhere. We estimate the analytical precision for Cl aerosol concentrations based on the standard deviation of many blank samples to be 2 ng m⁻³

The chlorine concentrations are shown as a percentage of fine aerosol mass in Fig. 1. The ratios of chlorine mass on the peak day to average chlorine mass for several days before and after the event are: Portage (76), Topeka (48), St Louis (28), rural Kentucky (43), rural Indiana (45) and rural Ohio (15). The peak chlorine concentrations in the fine aerosol fraction exceeded 1 µg m⁻³ at all locations except the easternmost site in Ohio. These are the highest fine aerosol chlorine concentrations that we have found among thousands of samples collected in urban and rural areas across the United States during the past 4 yr.

Two previously identified sources of elevated aerosol chlorine are road salting and vegetative burning^{2,3}, although these seem unlikely explanations for an event covering such a large area, they can be ruled out for other reasons, including aerosol properties. Elevated chlorine levels have been observed in aerosols after salting of roads to remove snow. After road salting, most of the chlorine is found in the coarse fraction; during the event reported here, however, the fine to coarse aerosol chlorine ratio was >2:1. City records show that roads

were salted in Portage on 2, 5, 23 and 29 December; in Topeka during 8-11 December and in St Louis on 23 and 24 December. These dates do not correspond to the observed event.

Vegetative burning causes marked increases in fine aerosol potassium. During the chlorine event, however, the potassium levels did not increase significantly in rural areas and decreased in the most polluted area, St Louis. Burning causes large increases in aerosol carbon; soot is an effective light absorber and renders the aerosol black. During the chlorine event, however, the blackness of the collected aerosol, as measured by light transmission of samples from the rural Indiana site, decreased by nearly an order of magnitude. Finally, when the chlorine aerosol levels increased, the total fine aerosol mass decreased by a factor of 2-3 in those areas where the fine aerosol is usually high due to industrial, residential and vehicle emissions (that is the sites at St Louis and rural Kentucky, Indiana and Ohio); this indicates ventilation by clean air. Ionexchange chromatography showed that the concentration of sodium in the samples from the rural Kentucky site began increasing on 19 December, reached a peak value on 20 December which was 10 times higher than the 17 and 18 December levels, and diminished on 21 and 22 December. The mass ratio of Cl⁻/Na⁺ on 20 December was 1.5, equal to the stoichiometric mass ratio for NaCl. These aerosol compositions are consistent with a large, very clean air mass having moved suddenly into the eastern United States, carrying fine aerosol sea salt.

The meteorological conditions associated with this chlorine event are best described as a typical wintertime cold outbreak. A large, cold, dry anticyclone moved over the area of interest and, by 07.00 h on 20 December, covered the United States east of the Rocky Mountains (all times here are Eastern Stan-

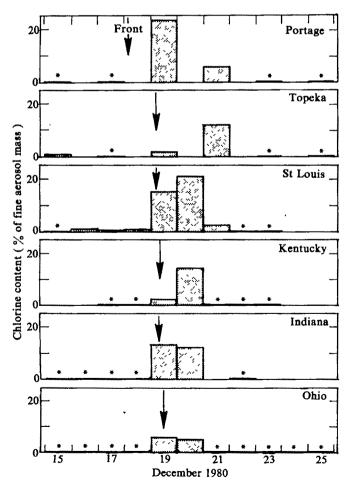

Fig. 1 Chlorine as percentage of fine-fraction aerosol mass collected during 24-h intervals. Note that samples were collected on odd-numbered days at Topeka and Portage. Asterisk indicates <0.5%.

dard Time, EST). The large-scale sinking motion (subsidence) accompanying the cold outbreak brought mid- and upper tropospheric air to lower levels as indicated by an isentropic trajectory analysis⁴. Such a trajectory, plotted backwards in time from 07.00 h on 19 December from a point over Salem. Illinois, showed that air which was at 850 mbar over Salem, was at 548 mbar over Whitehorse in the southern Yukon 48 h earlier. A second, simultaneous trajectory from Green Bay, Wisconsin did not show so much sinking but remained near 700 mbar and 48 h earlier was over Hudson Bay. Note that the trajectory at Salem is for air arriving only a few hours after the frontal passage, while that at Green Bay is for air arriving more than a day after the frontal passage. The stronger subsidence occurring at Salem is consistent with the view⁵ that the strongest subsidence in a cold outbreak occurs shortly after the frontal passage. Thus, the air arriving over our aerosol samplers at 07.00 h on 19 December came from mid-tropospheric altitudes and was over western and central Canada 48 h before. This air was mixed down to the surface by turbulence in the planetary boundary layer. The surface winds in the area of interest were between 5 and 10 m s⁻¹ on the day in question.

The chlorine concentrations reported here are less than those which have been observed in the marine boundary layer, but much larger than those observed in either the continental boundary layer or free troposphere^{6,7}. Consequently we infer that the aerosols are of marine origin. We have not ascertained the exact source of this air, but we speculate that the air was in contact with the open sea long enough to acquire marine characteristics, and was then transported by synoptic-scale motion to the observing sites. There is evidence that air does indeed move from surface to mid-tropospheric levels in frontal cyclones⁵, and we suggest that this rising motion, followed by motion described by the calculated trajectories, was responsible for our observations. Transport of clean air having maritime characteristics to a continental site is the reverse of the transport of continental crustal aerosol to remote marine sites⁸.

Although these observations of high, fine-particle chlorine concentrations are unique as far as we know, nothing in the meteorological conditions seems to distinguish this cold outbreak from others typical of the season. The explanation may be associated with the interesting behaviour of the sulphate component of the fine aerosols which we observed at the Indiana sampling site. Studies in urban areas and in rural areas of the eastern United States have shown that sulphate is generally the most abundant component in the fine aerosol and is largely in the form of ammonium acid sulphate or ammonium sulphate⁹⁻¹¹. Included at the Indiana site was an aerosol sulphate monitor which thermally separated and measured the relatively volatile and non-volatile sulphates in the fine aerosol at intervals of 30 min¹². The non-volatile sulphates are thought to be alkali metal and alkaline earth sulphates, whereas the volatile sulphates consist of ammonium sulphate and ammonium acid sulphate. Preceding the event at the Indiana site, the volatile to non-volatile sulphate ratio was ~2:1. Between 23.00 and 24.00 h on 18 December, the amount of volatile sulphate fell abruptly and the non-volatile sulphate decreased slightly, resulting in a volatile to non-volatile sulphate ratio of 1:4. On the night of 21 December, at the end of the chlorine event, the volatile sulphate began to rise to pre-event levels. It may be that, in most cases, chlorine is lost from marine aerosols transported over long distances inland by reactions with acid gases (nitric acid) and aerosols (sulphuric acid and ammonium acid sulphate). The reaction would release chlorine from the marine aerosol in the form of the volatile gas hydrogen chloride. In our observations the abrupt decrease in volatile sulphate before the chlorine event suggests that there was no reactive loss of chlorine from the incoming marine aerosols.

Thus we have observed a brief event of very high concentrations of fine-mode aerosol chlorine at six locations in the central and eastern United States. Presumably, this was the result of transport from the northern Pacific of marine aerosols in an air parcel which displaced aerosols characteristic of the region.

We thank Philip Haagenson of the National Center for Atmospheric Research for the trajectory calculations, John Spengler and his colleagues at Harvard for supplying some of the aerosol samples, and James Huntzicker and colleagues of Oregon Graduate Center for providing sulphate data. Samples in rural Kentucky, Indiana and Ohio were collected by Mead Technology for the US Environmental Protection Agency. Samples from Portage, Topeka, St Louis were collected by the School of Public Health, Harvard University. F.S.B. was on assignment from the National Oceanic and Atmospheric Administration.

Thermoluminescence reveals weathering stages in basaltic rocks

Y. Göksu Ögelman* & S. Kapur†

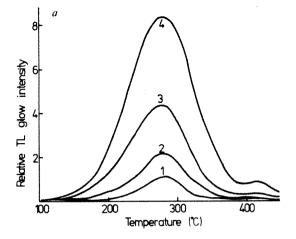

* Department of Physics and Space Sciences, † Department of Soil Sciences, Cukurova University, Adana, Turkey

The weathering of basaltic rocks is important in several regions throughout the world because of its soil forming capacity^{1,2}. Basaltic minerals alter to various types of clay minerals depending on the climatic and chemical conditions of the environment. Investigation of the weathering of rocks involves detailed work consisting of thin section and X-ray and electron microscopy techniques: alternative methods would be desirable. We show here that the thermoluminescence (TL) properties of weathered feldspars can be used as tracers of the relative weathering stages of basaltic rocks.

TL techniques have been used successfully to date pottery³⁻⁵. burned flints⁶, lava flows⁷, young ocean sediments⁸ and biological materials like bone and teeth9. Basically the technique involves the emission of visible light from heated crystalline material, as the electrons in traps are released and recombine with the holes. In minerals and rocks, the ionizing radiation, primarily from the naturally occurring radioisotopes of ²³⁸U, ²³²Th and ⁴⁰K, pumps the electrons into the traps. The TL efficiency and the radiation dose at which light emission of the material will saturate are a complex function of the ion vacancies, interstitial ions, impurities and dislocations that lead to the formation of traps with semicontinuous energy levels.

Using TL for measurement of geological age, however, has led to difficulties because of the complexity of the geological history involving structural stresses, recrystallization and nonthermal fading of high temperature peaks known as the anomalous fading 10

We initially tried to date samples collected from the parent materials of four sites in south-east Turkey, between Urfa and Siverek. However, their markedly different TL characteristics suggested that we should rather investigate their weathering properties. This region is composed of basaltic rocks of Tertiary age covering the northern part of Syria—the Syrian Shield. The

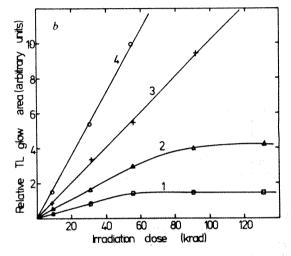

Fig. 1 a, Induced TL glow curves of weathered feldspar from four different profiles of the Karaca Mountain basaltic plateau. The irradiation dose was 55 krad and the heating rate 2 °Cs Low-temperature peaks were erased by preheating the samples at 80 °C for 5 s. b, Variation of TL glow curve area under the 275 °C peak as a function of the irradiation dose. The saturation doses were 55, 80, 130 and 300 krad respectively from layers 1 to 4. Points corresponding to high radiation doses of 3 and 4 are not shown. The numbers on the curves indicate their relative weathering in increasing order.

samples came from profiles typical of topographically and chronologically sequential continuations of different lava flow levels of the Karaca Mountain (1,919 m).

Feldspar grains, which are responsible for producing TL in basaltic rocks, were separated out from the samples. The basalts were viced in a V-shaped metal to extract feldspars without damaging them. They were then washed with HCl to dissolve the secondary CaCO₃ depositions in the vesicles. After dispersing the samples in Calgon overnight, grains of 100-150 µm size were separated by wet sieving. Lighter feldspar grains were extracted by floating them in bromoform. Aliquots of 5-mg feldspar grains were spread over 1-cm diameter aluminium disks for TL measurements. These samples were heated in an argon atmosphere from 100 to 480 °C at a rate of 2 °C s⁻¹ and natural TL glow curves were obtained. It was observed that during this process, the natural TL of all the samples was almost completely drained. Subsequently, varying radiation doses were given to the samples using a 200 mCi ⁹⁰Sr/⁹⁰Yr β source and glow curves were obtained 5 min later. Figure 1a shows the induced TL glow curves of the feldspar samples from the four different profiles of the Karaca Mountain basaltic plateau. Figure 1b shows the variation of the TL glow area under the 275 °C peak with radiation dose. Each point represents the average of four measurements from each sample. The TL sensitivities of the samples were obtained by plotting the linear

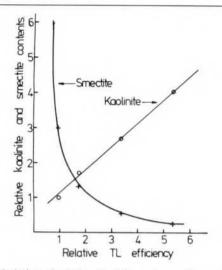

Fig. 2 Variation of relative kaolinite and smectite content with TL efficiency.

portion of the graphs of radiation dose against the area under the 275 °C peak; the saturation dose levels were determined from the asymptote of the curves.

The products from weathering of the same samples of feldspars were observed by polarizing microscope and X-ray diffraction techniques. The relative kaolinite and smectite contents were determined by measuring the area under the 7.2 Å and 18.0 Å peaks respectively, of powdered X-ray diffractograms.

Figure 2 summarizes the relative behaviour of kaolinite, smectite contents of weathered feldspars with respect to TL efficiency. As weathering progresses the kaolinite content increases, the smectite content decreases, and the TL efficiency and saturation dose level increases.

Figure 3 shows a thin section of the basalt from profile 2, covered with feldspars. Weathering can be observed as the cracking of the twinning planes as well as the formation of weathered regions (clay minerals) on the surface. Therefore, it is unlikely that improvement of optical transmission properties could account for the increased TL efficiency. Because the TL efficiency is proportional to the density of lattice defects, it is likely that weathering increases the defects on the surface of feldspars. Scanning and transmission electron microscopy could help to estimate the type of defects produced during the transformation of feldspars to clay with the TL method.

TL is a quick and cheap method compared with the usual lengthy mineralogical procedures for determining the relative

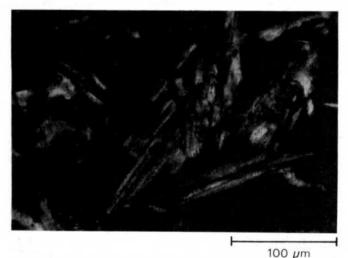

Fig. 3 A thin section of one of the basalt rocks with moderately weathered feldspar grains from profile 2. Weathering can be observed as the cracking of their twinning planes as well as the formation of weathered regions (clay minerals) on the surface.

stages of weathering in basaltic rocks. Conversely, the TL characteristics of weathered basaltic rocks in the same regions or similar climatic and chemical environments, can be used to determine their relative ages. These concepts could be extended to other weathered rock materials.

We thank the Turkish Scientific and Technical Research Council for supporting this research through the Archaeometry Study Group. Y.G.Ö. further thanks her fellow prisoners for friendship and understanding, and her husband whose continued love and support eased the agony of life in prison and made the completion of this article possible.

A premonitory pattern of earthquakes in northern Greece

B. C. Papazachos, T. M. Tsapanos

& D. G. Panagiotopoulos

Geophysical Laboratory, Aristotelian University of Thessaloniki, Thessaloniki, Greece

On 20 June 1978 at 20 h 03 min 23 s, an earthquake of surface wave magnitude 6.5 occurred in the Migdonian basin, between the Lagada and Volvi lakes, and 26 km from Thessaloniki. The main shock was preceded by a seismic sequence which started on 8 May. The largest earthquake of that sequence occurred on 23 May and had a surface wave magnitude of 5.8. The long duration of this sequence before the main shock of 20 June had tremendous psychological effects on the whole country. Greek seismologists were in a difficult position during that time (8 May-20 June), especially after the earthquake of 23 May, when pressed to state whether these earthquakes were foreshocks or aftershocks. Long-lasting seismic sequences with earthquakes of magnitude <6 are common in the Aegean area. Because these sequences are sometimes followed by large earthquakes it is important to see whether the latter can be predicted. The May-June 1978 seismic sequence provided the opportunity for testing hypotheses about statistical properties which, it has been suggested, could distinguish between foreshocks and aftershocks. This particular sequence has been investigated extensively 1-4 and more accurate data are available than for any other sequence around Greece. Focal mechanism studies5,6 and field observations² showed that the largest earthquakes of the sequence were produced by horizontal extension in a nearly north-south direction and that the main rupture occurred on a normal fault which strikes almost east-west and dips to the north. The fault length of the main shock of 20 June was estimated7 to be 32 km. Accurate determination of earthquake foci, using portable seismographs, showed that the earthquakes of this sequence were shallow (h < 17 km) while the distribution of the epicentres had a very clear east-west elongation 4.5. A migration of the seismic activity from east to west has also been observed between 8 May and 14 July. We investigate here the time variation of the average magnitude and the frequency of all the shocks with $M \ge 3.0$ of this sequence. The time variations of these seismic parameters are examined in connection with the distribution of well determined epicentres of 38 earthquakes with $M \ge 4.3$ in order to search for any premonitory pattern of the 23 May and 20 June major earthquakes.

Accurate epicentre and focal depth determination for large and small earthquakes of the sequence exist for the period after 3 July 1978 when the first network of portable stations was put in operation in the epicentral region by D. Carver and R. Henrisey of the US Geological Survey. Two other such networks were put in operation, one on 20 July by a team under G. King of Cambridge University in cooperation with the Geophysical Laboratory of the University of Thessaloniki, and another on 1 August by the Public Power Corporation of Greece (PPC). However, one portable seismograph run by the Geophysical Laboratory was in operation in Thessaloniki for the period 26 June-2 July.

For the period 8 May-2 July, the available data come from the network of permanent stations of Greece and neighbouring countries and from a network of three permanent stations of PPC. The closest of these stations are PLG ($40.37\,^{\circ}N$, $23.45\,^{\circ}E$) at a mean distance of $40\,^{\circ}km$ south of the epicentral region, VAY ($41.32\,^{\circ}N$, $22.57\,^{\circ}E$) at a mean distance of $90\,^{\circ}km$ north-west of the epicentral region and the network of the three stations of PPC (KAP: $40.36\,^{\circ}N$, $21.98\,^{\circ}E$, POL: $40.31\,^{\circ}N$, $22.11\,^{\circ}E$, SER: $40.18\,^{\circ}N$, $22.01\,^{\circ}E$) at a mean distance of $\sim 110\,^{\circ}km$ south-west of the epicentral region.

As there was continuous recording from the three PPC stations during the whole sequence, their records were the basis for the present investigation of the time distribution of the earthquakes between 8 May and 2 July. The magnitudes of all these earthquakes were determined using relations of the form M = $a \log \delta t + V \Delta + c$, where, Δ is the epicentral distance⁸ and δt is the signal duration⁸. The constants a, V and c were determined by the usual statistical procedure for earthquakes for which M was known by other means. These formulae were used to determine a magnitude for each station and the average of the three determinations was taken as the magnitude of each earthquake. Magnitudes down to 2.6 were found. In attempting to determine the epicentres for all the earthquakes, we found that for those with $M \ge 2.8$ we could decide whether their epicentres were in the epicentral region of the sequence or elsewhere. However, we finally decided to include in our catalogue and use in this study only earthquakes with $M \ge 3.0$. In this way we have a catalogue of complete and homogeneous data with respect to magnitude for the whole period of the sequence. Between 8 May and 2 July, the number of shocks with $M \ge 3.0$ was 393. This catalogue will be published elsewhere.

The statistical relationship $\log N = a - bM$ between the number, N, of earthquakes which have magnitudes equal to or larger than a certain value and this value, M, holds also for seismic sequences (foreshocks, aftershocks, swarms). The parameter b in the frequency-magnitude relationship is smaller for foreshocks than for aftershocks^{9,10}; laboratory experiments have shown that this can be attributed to the homogeneity of the material¹¹ or to the high stress level¹² in the focal region during the foreshock period. That is why the low values of b have been suggested as precursors of strong earthquakes¹³. However, it is not easy to determine b accurately for several time intervals to follow its pattern, thus the time variation of other parameters, which are related to b but are easily and accurately determined. can be examined to see whether they establish any premonitory patterns of strong earthquakes. The difference in magnitude between the main shock and the largest aftershock has been suggested14 as such a parameter.

We now present evidence that the time variation of the average magnitude value could be considered as premonitory pattern of the 23 May and 20 June 1978 earthquakes. Relationships between \overline{M} and the parameter b have been derived by Hamilton¹⁵ and Utsu¹⁶. Utsu gave the following simple formula:

$$\bar{M} = \frac{\log e}{b} + M_{\min} \tag{1}$$

where $\log e = 0.4343$ and M_{\min} is the magnitude of the smallest earthquake considered. This relation shows that \bar{M} must have relatively large values for foreshocks and smaller values for aftershocks.

The time variation of the average magnitude of this sequence was determined as follows: a minimum number k of events was defined and, for each day, the average of all earthquake magnitudes, with $M \ge M_{\min}$ was taken as the mean magnitude \bar{M} when the number of events n of that day was $\ge k$. When a day had a total number of considered events n < k then the k - n events were taken from its previous day (or days). In this way, each value of \bar{M} was determined with k or more observations.

Such calculations of M were made with all earthquakes in the catalogue $(M_{\min} = 3.0)$ and k = 10. The calculations were repeated with k = 15. Plots of \bar{M} against time have shown that the whole seismic sequence can be separated in four subsequences. These sub-sequences cover the periods 8 May-23 May-1-20 June-2 July, during which the \vec{M} values are 3.67, 3.35, 3.61, 3.48 and the corresponding number of shocks with $M \ge 3.0$ are 24, 57, 65, 247, respectively. This means that the average values of magnitudes are relatively high-low-high-low during these four consecutive time periods. Unfortunately no data exist to determine the average magnitude for the background seismic activity of the area. These data will become available in the next few years because the Geophysical Laboratory installed a telemetry network of eight seismic stations in the area on 1 January 1981. The calculations were repeated with other values of M_{\min} (3.1, 3.2). The decrease in the sample number had some effect on the plots but the basic pattern remained unchanged.

Figure 1a shows the time variation of \bar{M} for k=15 and $M_{\min} = 3.0$. The values for the period 8-13 May have not been plotted because there are not enough data (n < 15) to determine \bar{M} with the accuracy of the other plotted values, but the values

for this period are clearly high because only shocks with $M \ge 3.2$ occurred during this time. The time of occurrence of the two major earthquakes of 23 May (M = 5.8) and of 20 June (M = 6.5) are also shown in Fig. 1a, while in Fig. 1b the frequency (daily number) of earthquakes with $M \ge 3.0$ as a function of time is shown.

From Fig. 1 we see that during the two aftershock periods (23 May-1 June, 20 June-2 July), when the mean frequency of earthquakes decreases with time, the average magnitude values are clearly low. The mean of the average magnitudes of these periods is 3.38 with a s.d. of 0.06. During both the 15 days before the earthquake of 23 May and during the 19 days before the earthquake of 20 June, the mean magnitude values are clearly high. The mean of the average magnitudes of these two periods is 3.60 with a s.d. of 0.08. It seems, therefore, that the 23 May earthquake was preceded by its foreshocks and followed by its own aftershocks. The latter were distinct from the foreshocks of the 20 June earthquake. The standard deviations above mentioned have been multiplied by 1.6 to determine approximately the 90% confidence intervals. The three horizontal dashed lines in Fig. 1a show these 90% confidence intervals. The upper limit of this interval for the aftershocks coincides with the lower limit of this interval for the foreshock period.

The high values of \overline{M} during the whole seismic period before the earthquake of 23 May as well as during the 19 days period before the earthquake of 20 June could be considered as precursors of these two earthquakes. Similar observations in the future could possibly be used as a warning signal.

The frequency of aftershocks after the main shock of 20 June reached its first minimum on 2 July and therefore the earthquakes which occurred during this period can be considered as

real aftershocks. That is why we considered here only shocks which occurred up to 2 July. The number of shocks with $M \ge 3.0$ for the periods 3-31 July, 1-31 August and 1 September-31 December 1978 was 19, 26 and 31 respectively. That is, the number of shocks are less than one event per day even for July and August. So, it is impossible to determine reliable daily values of \bar{M} and plot them. Instead, the mean magnitudes for each of these periods have been determined and values of 3.49, 3.49 and 3.43 have been found. These values are within the 90% confidence intervals for aftershocks but are relatively high, especially the first two. This is probably due to the expansion of the activity to the west during July and to the east during August in areas which were not previously affected and some earthquakes of these periods considered as aftershocks of the 20 June event were probably foreshocks of second order sequences.

Unfortunately, no network of portable seismographs was operating in the epicentral area before 3 July with which to investigate the space-time distribution of a large number of earthquakes during 8 May-2 June. However, some of the largest earthquakes of this period have been determined accurately^{3,4} using the joint epicentre method. As these determinations are not sufficient to show the space-time distribution of the earthquakes which occurred before 3 July 1978, we have attempted to determine as accurately as possible the epicentres of all earthquakes of the sequence with magnitudes larger than a certain value. For this purpose the Hypo 71 program has been used with a three layer crustal model which is usually applied to determine epicentres in the Aegean area. To increase the accuracy, time delays determined from data of earthquakes recorded by portable seismographs (after 2 July) were added to the arrival times at the permanent stations in Greece and

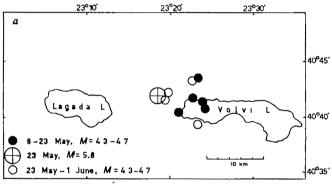

^{*} Our determinations.

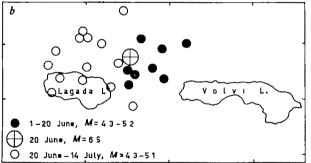

neighbouring countries. It was found that the epicentres of all shocks of the sequence with $M \ge 4.3$ were determined with standard errors ≤4 km. On the other hand, comparison of 20 epicentre determinations made by this method and the determinations of the same epicentres by other methods and data (joint epicentre, portable seismographs) showed very good agreement.

Table 1 gives information for all earthquakes of the sequence with $M \ge 4.3$. The number of observations, N, used to determine the focal coordinates, and the standard error, s.e., of the epicentre are given. All these 38 epicentres are plotted in Fig. 2.

The epicentre of the earthquake of 23 May as well as the epicentres of its largest $(M \ge 4.3)$ foreshocks and aftershocks are shown in Fig. 2a. The epicentres of these earthquakes (8 May-1 June) are located in the eastern part of the seismogenic volume of the entire sequence, near the western coast of the Volvi lake.

Figure 2b shows the epicentre of the main shock of 20 June, the epicentres of the largest $(M \ge 4.3)$ earthquakes which occurred during the 19 days period which preceded this earthquake (1-20 June) and the epicentres of the largest $(M \ge 4.3)$ earthquakes of the period 20 June-14 July. The largest earthquakes of the period 1-20 June had epicentres in a volume close to the epicentre of the main shock north of the area between the two lakes. This supports the idea that these earthquakes are real foreshocks of the earthquake of 20 June. Note that the largest two of these foreshocks occurred near the beginning (2 June, M = 4.9) and the end (19 June, M = 5.2) of this period and were located very close to the epicentre of the main shock. The largest aftershocks of the 20 June earthquake

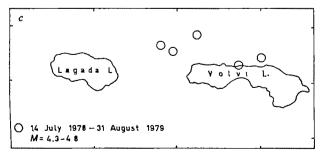

Fig. 2 Epicentres of all earthquakes of the sequence with $M \ge 4.3$ for the periods 8 May-1 June, 1978 (a), 1 June-14 July, 1978 (b) and 14 July, 1978-31 August 1979 (c).

which occurred for 23 days after the main shock were located further west in a volume clearly different from the foreshock volume. Such a westward migration of seismic energy release is also clearly shown in the distribution of the macroseismic intensities.

Figure 2c shows the epicentre distribution for the largest $(M \ge 4.3)$ earthquakes which occurred after 14 July 1978. Note that the main activity during this period shifted to the eastern

The distribution of epicentres shows clearly that between 23 May and 1 June only the eastern part of the seismic volume was active. During this period as well as during the rest of the time until the occurrence of the main shock, the central part of the area, where this main shock of 20 June was located, was in very high stress condition. Because the main seismic activity of the period 1-20 June occurred in this central part of the seismic volume in high stress conditions, high values of \bar{M} (low values of b) are expected during this period. Therefore, the high M values (or low \hat{b}) as well as the space-time distribution of the earthquakes which occurred between 1 and 20 June show that these are real foreshocks. If this information had been known in June before the main event (M = 6.5) it would have helped seismologists to predict that the danger was not then over.

We thank the Public Power Corporation of Greece for use of the records from its stations.

Direct evidence of a subducted plate under southern Mexico

C. Lomnitz

Instituto de Investigaciones Matemáticas Aplicadas y en Sistemas. Universidad Nacional Autonoma de Mexico, Mexico 20, D.F.

The hypothesis1 of subduction of oceanic plates under active continental margins has become a fundamental idea in plate tectonics. Yet the evidence for the existence of oceanic plates beneath continental borders is still largely circumstantial. In seismology, the presence of a new layer or structural unit is taken as confirmed only after seismic phases corresponding to reflections or refractions from that layer have been identified on selsmograms. I report here the presence of a mantle phase, interpreted as a seismic wave refracted from a dipping interface on records of aftershocks from the intermediate earthquake of 24 October 1980 in the Mixtec Highlands of south-central Mexico which may be direct evidence on the structural position of the subducted plate under the Mexican active continental margin.

The destructive earthquake of 24 October 1980 in the Mixtec Highlands ($M_L = 7.4$, h = 70 km) generated over 50 aftershocks

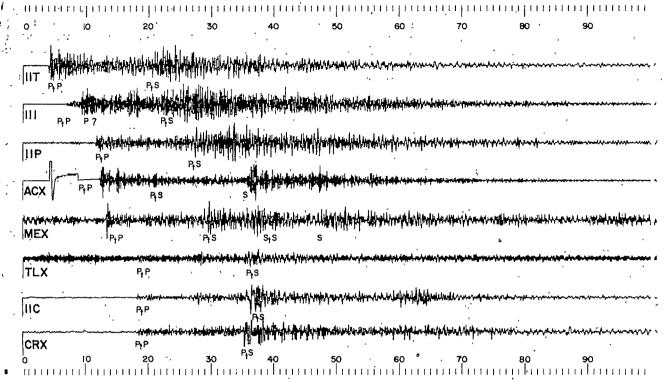

Fig. 1 Seismograms of aftershock 15:076° of the RESMAC catalogue, showing plate phases. All records are from 1-Hz vertical instruments (time in seconds).

which were large enough to be recorded and located on the RESMAC telemetric network. On each record a prominent arrival is found between 10 and 20 s after the initial P signal (Fig. 1). This phase cannot be identified as S, in spite of its low-frequency content, because S is expected to arrive (and is actually seen on most seismograms) 10 or more seconds later. It is not a P-to-S conversion at the bottom of the crust, as this would require a crustal thickness of >100 km and a refraction profile measured in this region in 1975 reveals that the crust is ~40 km thick² (S. K. Singh et al., in preparation).

The possibility that the mantle phase, which we call P_tS, might represent a crustal phase must first be discarded. The focal depth

of 70 km reported by Boulder on the strength of depth phases has been questioned²; however, independent evidence on the focal depth of the aftershocks exists from the records of a four-station temporary network operated in the epicentral region by the Institute of Geophysics of the National University of Mexico (R. Mota, in preparation). The S-P times at the nearest station are typically 7-10 s, indicating (if 40 km is the correct crustal thickness) a range of 55-85 km in focal depths of the aftershocks. If the aftershock activity had been in the crust, S-P times of <6 s should have been observed. The character of the seismograms also indicates a focus below the crust, because of the sharp P-onsets and the absence of the crustal arrivals

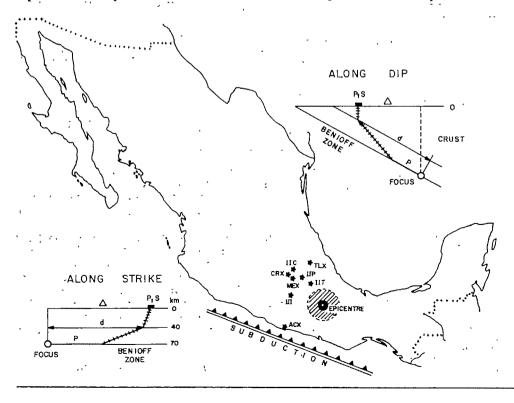

Fig. 2 Location map of RESMAC network in relation to the epicentral region, and proposed path of head wave P_tS refracted from the subducted Cocos Plate. Δ, epicentral distance; d, reduced distance for the same station.

which are typically found on seismograms from shallow events in this region.

The prominent amplitude and low-frequency content of the new phase suggest the presence of a refractor or waveguide at some depth below the crust. If the focus of the earthquake is within or close to the waveguide much of the seismic energy can be trapped and later refracted upwards as P or as S. This waveguide has exactly the structural position and velocity expected for the subducted Cocos Plate. Thus no plausible mechanism except subduction will account for the observations (Fig. 2).

Consider first the conventional travel-time plot constructed for the aftershock (Fig. 1). This event (25 October 1980 at 09:54:38UT) was relocated at 17.98° N, 98.12° W with the aid of the temporary stations. The travel times (Fig. 3) reveal that the apparent velocity of the second arrival is $\sim 8.0 \text{ km s}^{-1}$, too high for any direct or refracted second arrival from a layered crustal model. The expected arrival times for P_g and S_n are shown for comparison. Moreover, the converted P-to-S phase should arrive earlier, that is 6 s after the direct P arrival. Note that the fit of some individual arrivals is poor, notably for the coastal station ACX (Acapulco).

Assuming that the observed second arrivals represent a mantle phase, I present two different models for a deep refractor with a P-velocity of 8.2-8.5 km s⁻¹, corresponding to the bottom of the subducted oceanic crust (Fig. 4). First a simplified model is assumed involving two parallel dipping interfaces. The upper interface is the continental Moho and the lower interface is the oceanic Moho within the subducted plate (Fig. 4a). The geometry is such that the oceanic Moho crops out along the trench axis and the crustal thickness is 40 km at the epicentre. Moreover, the focus of the earthquake is assumed to lie at a depth of 70 km, precisely near the bottom of the subducted oceanic crust. The abscissae are distances measured along the dipping continental Moho, not along the surface of the Earth (see inset, Fig. 4a). In other words, the 'reduced distance' is the intercept of the refracted ray on the continental Moho, used as a datum plane. The Earth's surface cannot be used as datum because the refracted wave fronts describe a set of confocal ellipses on the surface: hence the plotting distance for a given wavefront varies with azimuth, and no rectilinear travel-time plot would be obtained.

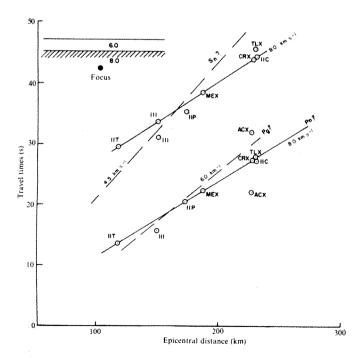

Fig. 3 Travel-time plot for a focus below the crust. Second arrivals do not fit any known phase. Note the poor fit of ACX.

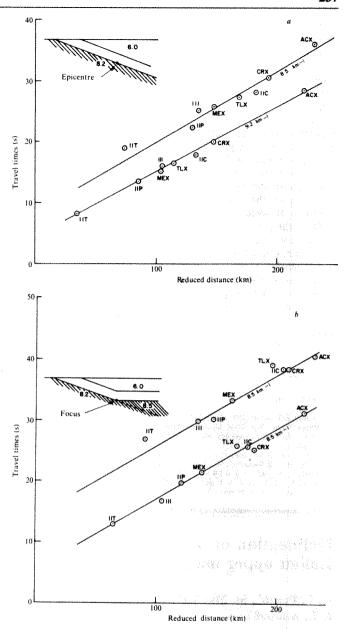

Fig. 4 a, A structural dip of 17° inland from the Mid-America Trench produces a good fit of the data, though the apparent velocities do not check with the model. b, A dipping subduction zone which levels off inland. The second arrival at III is doubtful (see Fig. 1), and might correspond to a direct S. Note that the apparent velocity of second arrivals is independent of the model.

A notable improvement of the travel-time fit is obtained by letting the deep refractor level off inland, as shown in Fig. 4b. This structural position was suggested by recent findings from refraction experiments on the coast of Colombia³. A slightly higher velocity for the inland position of the refractor $(v_p = 8.5 \text{ km s}^{-1})$ was assumed to conform with the Colombian results, though this is not an essential feature of the model. The apparent velocities of both refracted waves $(P_t P$ and $P_t S)$ are now equal and consistent with the model.

Mantle phases from intermediate and deep-focus earth-quakes had previously been observed in Tonga, Japan and Peru⁴⁻⁸, though most of this work describes individual arrivals of phases other than P_tP or P_tS. The RESMAC array in central Mexico is well placed for observations of deep mantle phases; the apparent velocities of the phases can be determined and the approximate structural position of the deep refractor can be inferred. This proof of subduction is particularly convincing to the seismologist as it complements the structural information obtained from offshore explosions recorded on land.

The refractor is tentatively identified as the bottom of the subducted oceanic crust. The oceanic crust itself has a lower velocity, perhaps of the order of 6.8 km s⁻¹. If no such lowvelocity lid existed the refractor would not function efficiently as a waveguide.

Consistently similar seismograms were recorded for over 50 aftershocks of the 1980 Mixtec earthquake. Similar deep refractions have also been observed on other Mexican intermediate-focus seismograms written on the RESMAC array. So-called 'early S-phases' recorded at local stations for the destructive Puebla-Veracruz earthquake of 28 August 1973 (h = 84 km) can probably be interpreted as P.S. The present work demonstrates the potential of mantle phase observations for mapping the structural position of subducted plates under continental borders

Does the subducted Cocos Plate level off inland, as indicated by the model of Fig. 4b? Earthquakes under the coastal plain of Veracruz, east of the Mixtec epicentre of 1980, typically have focal depths in the range of 80-100 km suggesting that the Benioff zone does indeed level off, because substantially greater depths would be expected for a uniformly dipping model as shown in Fig. 4a. Future studies of PrS observations from intermediate shocks in Veracruz should help resolve this question.

The RESMAC seismic network is supported by a grant of the Consejo Nacional de Ciencia y Tecnología of the Government of Mexico.

Delineation of the North Central Italian upper mantle anomaly

G. F. Panza*, St. Mueller†, G. Calcagnile‡ & L. Knopoff§

The Italian peninsula is the focus of intense deformational tectonic activity. It is underlain by mantle material whose inferred, relatively anomalous properties^{1,2} are not inconsistent with the seismic, volcanic and thermal activity that is manifested in this region. The most effective geophysical tool for mapping the structure of the uppermost 200-300 km of the Earth is the observation and analysis of seismic surface-wave dispersion on a regional scale. Here we synthesize the interpretations of Rayleigh wave dispersion measurements made by several authors, each for different parts of North Central Italy3delineate the lateral extent of the upper mantle anomaly in this

Over the past 20 years intensive efforts have been made to study details of the cross-section of the crust and upper mantle in the European-Mediterranean area. As a result of these studies, several zones were delineated^{1,2}, such as the Western Mediterranean, the Tyrrhenian Sea, the Adriatic promontory of the African plate and the Central European Rift System, each with differing mantle structure. In addition to these struc-

Surface wave paths relevant to this study. The shaded region is the location of the mantle anomaly in North Central Italy.

tures, another conspicuous anomaly can be identified under the north-central part of the Apennine peninsula, that is the tectonically active region to the east and north of Corsica.

The properties of the upper mantle under North Central Italy (Fig. 1) have been delineated by Rayleigh wave dispersion measurements along two profiles TNO-AQU and TRI-OLB^{5,6} These profiles have unusually low phase velocities in the period range 40-60 s (Fig. 2). Velocities as low as these have been observed in the Western USA9, as, for example, on the path TUC-BOZ, and the East African Rift¹⁰, both regions of high heat flow. The correlation between the surface wave phase velocities in northern Italy and high heat flow is even stronger after the phase velocities have been inverted; cross-sections are found consistent with the absence of a lid to the low-velocity channel (Fig. 3) and anomalously low S-wave velocities that extend up to, or close to the Mohorovicic discontinuity. In these cases the high surface heat flows are probably thus derived from high temperatures at shallow depth in the mantle and hence are a surface expression of tectonic involvement on a scale extending into the mantle.

The phase-velocity profile TNO-AQU (Fig. 2) differs in shape from the other two examples and would seem to provide an example of the danger of a literal interpretation of phase velocity curves in the period range 40-60 s. This curve differs from the others because of the influence of a larger crustal thickness under the axis of the Apennines than in the other regions described by low-phase velocities. Inversion of this phase velocity curve indeed indicates that a lid to a low S-wave velocity channel is absent⁵, and that this curve is properly catalogued with TRI-OLB, TUC-BOZ and others.

We can provide a rough limit to the lateral extent of the Italian anomaly. To the south, the region is abutted by the Tyrrhenian Sea and still farther south by the Sicilian crossing of the Mediterranean by the contact between the African and European plates. High heat flows, volcanism, low surface-wave phase velocities, deep focus earthquakes, and an inferred subduction¹¹ give the Tyrrhenian region the appearance of a backarc basin. Thus the anomaly of the northern Italian peninsula seems to continue southward; the southern limit to the Tyrrhenian extension of the anomaly would appear to be at or

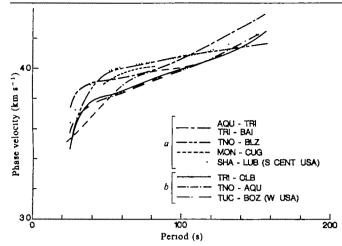

Fig. 2 Phase velocities used to delineate the North Central Italian anomaly and comparison with dispersion relations for western and South-Central USA. The r.m.s. errors for each curve are $\sim \pm 0.03 \text{ km s}^{-1}$ in the period range 40-60 s and are larger at the extremes of the period range $^{3.5-9}$. Curves in group a are for regions without tectonic involvement and in group b for regions with tectonic involvement.

near the plate boundary with North Africa. An exploration of this region will be described elsewhere.

To the west, surface-wave profiles near Corsica and Sardinia on path MON-CUG³, as well as to the north in the Italian Alpine foothills on path TNO-BLZ^{4,7}, have shown rather higher phase velocities in the period range characteristic of mantle depths. Similar phase velocities have been found elsewhere in relatively older, stable continental regions with more-or-less normal heat flows, that is, regions without major tectonic involvement today^{9,12,13} including the US Gulf Coast, such as on path SHA-LUB, and Western Europe. While inversion of these latter phase velocities may differ in some detail, especially in view of the non-uniqueness of the inversions, all successful inversions yield an upper mantle cross-section which has a broad low-velocity channel of significant contrast to an overlying high-velocity lid (Fig. 3); the channel-lid interface is found around a depth of 100 km. As indicated, this cross-section is evidently well correlated with the age and stability of these regions, characterized by their 'normal' heat flows and relatively

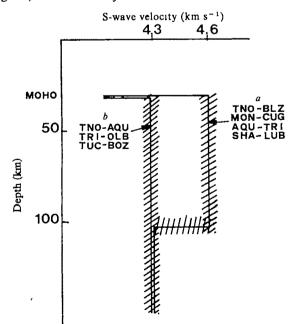

Fig. 3 Schematic shear wave velocity-depth distributions in the upper mantle for regions without a and with b major tectonic involvement today. The shading represents schematically the range of models satisfying each group of dispersion data.

low seismicity.

The values of phase velocities at periods between 40 and 60 s are diagnostic between the two groups. The errors in measurement are in every case less than the phase velocity interval between the groups of curves. It follows that the inversions of these phase velocity data yield structures for the two typical regions that are completely resolved from one another; the differences between the geophysical and geological environments of these two groups of regions are equally large.

The eastern edge of the Italian anomaly is delineated by surface-wave phase velocities that were determined along two Adriatic two-station paths, TRI-BAI and TRI-AQU⁸. The two phase velocity curves are indistinguishable over their common period range and are plotted as a single curve in Fig. 2. They are clearly members of the family of curves associated with young, stable continental regions, such as those for Western Europe. Such regions have well defined lids to channels. Crosssections such as those for northern Italy, in which high-velocity lids are absent, are excluded. The inversion of these curves is no different, within errors of measurement, from those derived for other regions and sketched in Fig. 3.

We conclude that the anomalous low phase velocity region of northern Italy lies to the east of the path MON-CUG, to the west of the path AQU-TRI, and south of the Alps.

Pb isotopic composition of ophiolitic volcanogenic sulphide deposits, Troodos Complex, Cyprus

E. T. C. Spooner

Department of Geology, University of Toronto, Toronto, Ontario, Canada M5S 1A1

N. H. Gale

Department of Geology and Mineralogy, University of Oxford, Parks Road, Oxford OX1 3PR, UK

The volcanogenic sulphide ore deposits in the ophiolitic rocks of the Troodos Massif, Cyprus, are thought to be ~80 Myr old¹ analogues of the metal sulphide accumulations actively being deposited from ~350 °C water at a depth of ~2.6 km on the East Pacific Rise (21°N)²⁻⁴. In both cases, mineralization is thought to be a consequence of heat transfer by convective seawater circulation within the oceanic crust^{5,6}. Evidence includes fluid inclusions in quartz from ore deposits in Cyprus with modal trapping temperatures of 298-370 °C which have a bulk composition of 3.2 \pm 0.5 equiv. wt % NaCl (1 σ ; n=273). This salinity is identical to seawater with 3.5 wt% total dissolved solids^{4,7}. We have examined the isotopic composition of Pb as a geochemical tracer to clarify the origin of one of the metals contained in the sulphide concentrations in the Troodos Complex. It was anticipated that the bulk of the lead would have been derived by leaching of the mafic ophiolitic rocks and, indeed, such a component is found to be present. However, the isotope ratios suggest that the lead is actually a mixture, and also contains an important component derived from seawater.

Interpretation of the isotopic data for the sulphides requires a knowledge of the isotopic characteristics of the associated igneous rocks of the ophiolitic complex. Hence, Pb isotope ratios were determined for a suite of eight variably ocean floor-metamorphosed basalts, dolerites and gabbros, the precise locations of which are given in Table 1 together with the results. Initial $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ ratios were determined to monitor the degree of seawater-rock interaction which might also have affected the Pb isotopic composition, as this process is associated with increases in the $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ ratios of altered rocks above initial magmatic $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$ ratios of 0.70338±0.00010 to 0.70365±0.00005 (ref. 8).

Sulphide Pb isotope ratios were determined for 11 samples from five deposits (Table 2). In addition, a single independently obtained set of values is available for Skouriotissa9. As can be seen in Fig. 1, these six deposits give good spatial coverage of the Troodos Complex. In general terms, the sulphide concentrations consist of lenses of massive ore intercalated conformably. within the pillow lava succession which are underlain by mineralized stockworks⁴. Massive ore is thought to have precipitated on the actual ocean floor from hydrothermal solutions which discharged through the stockworks beneath, and was deliberately avoided in this study because of possible complications associated with high level seawater mixing. Hence, most of the samples (10 out of 12) are from stockworks some of which are deep (for example, Alestos; ~1km), others being relatively shallow (for example, Mathiati; ~40 m) relative to the original ocean floor. Two samples from the Limni mine in western Cyprus were mill concentrates and represent an average of the ore being processed at the time. All the other materials analysed were sulphide separates consisting mainly of pyrite and chalcopyrite produced from ~0.5 kg samples.

As shown in Fig. 2, most of the lead isotope compositions of the ophiolitic mafic rocks fall in, or near, the fields for mid-ocean ridge basalts¹⁰, or are less radiogenic. Some very low Pb isotope ratios were determined. For example, two gabbros (T74 and T137) have 206Pb/204Pb, 207Pb/204Pb and ⁸Pb/²⁰⁴Pb ratios of 16.620 and 17.050, 15.401 and 15.481, and, 36.511 and 36.801, respectively. A metadolerite (CY/75/80) has ratios of 17.398, 15.370 and 36.930. These values are all distinctly less radiogenic than any presented by Tatsumoto¹⁰. For some reason, two of the samples (CY/75/73 and 94B) seem to have slightly higher ²⁰⁷Pb/²⁰⁴Pb ratios than is typical (Fig. 2b). The Pb isotopic compositions of most of the samples are not likely to have been significantly affected by seawater interaction because sample CY/75/80, a metadolerite dyke with a contaminated initial 87Sr/86Sr ratio of 0.70505±0.00003, has unradiogenic Pb isotope ratios similar to fresh gabbros with initial 87 Sr/ 86 Sr ratios of 0.70357 ± 0.00006 and 0.70362 ± 0.00006 , and a metabasalt sample (CY/75/75; no. 1 in Fig. 2) with a low initial 87Sr/86Sr ratio of 0.70342 ± 0.00003 has Pb isotope ratios which are near the radiogenic end of the defined range. In addition, the most Sr-isotopically contaminated sample (CY/75/94B; no. 8 in Fig. 2), with an initial ${}^{87}Sr/{}^{86}Sr$ ratio of 0.70585 ± 0.00003 , has initial Pb isotope ratios which are slightly less radiogenic than sample CY/75/75 (no. 1) discussed above. A possible exception is sample CY/75/71 (no. 7 in Fig. 2) with the most radiogenic Pb isotope ratios which plot between the mid-ocean ridge basalt fields and the seawater fields. This sample was notable because it contained a prominent hydrothermal epidote-sulphide vein which could have contained Pb dissolved in the circulating fluid of seawater origin. The Pb isotopic composition of the ophiolitic mafic rocks of the Troodos Complex is apparently comparable with that of mid-ocean ridge basalts, but also extends to lower

The Pb isotope ratios of the 11 sulphide separates from five ore deposits analysed in this study are more radiogenic than those for the ophiolitic mafic rocks (Table 2 and Fig. 2). The following ranges are defined: $^{206}\text{Pb}/^{204}\text{Pb} = 18.404-18.888;$ $^{207}\text{Pb}/^{204}\text{Pb} = 15.551-15.634;$ $^{208}\text{Pb}/^{204}\text{Pb} = 38.271-38.743.$

Rb and Sr were determined by X-ray fluorescence on a Philips 1410 instrument²⁰. Sr was extracted using standard ion exchange techniques and its isotopic ratio was analysed on a V.G. Micromass 30 mass spectrometer²¹. As all samples were found to have Rb/Sr ratios <0.02 age correction to 80 Myr BP, the age of the Troodos Complex¹, was unnecessary. Quoted errors are 2 s.d. and are ≤ 0.00005 . All results are quoted relative to an Eimer and Amend SrCO₃ standard isotopic ratio of 0.70800. The mean Eimer and Amend 87 Sr/ 86 Sr ratio measured in this work was 0.70807 ± 0.00002 . Pb was extracted using anodic electrodeposition²² and its isotopic composition analysed with a 12-inch radius mass spectrometer using a standard silica gel-phosphoric acid technique which yields ratios accurate to better than $\pm 0.1\%$. The values have not been age corrected to 80 Myr BP using independently determined U/Pb and Th/Pb ratios. Hence, initial ratios would be less radiogenic.

Pb concentrations were determined by mass spectrometric isotope dilution with an accuracy of $\pm 2\%$. Either a solvent extraction step using methylisobutylketone (MIBK) or an HBr anion ion exchange column was used to remove Fe before extraction of lead by anodic electrodeposition²². Isotopic analysis was carried out by the method described in Table 1. Age correction to 80 Myr BP was unnecessary as sulphides contain very low levels of U and Th relative to lead.

* From ref. 9.

Lead in the sulphide separates is present at trace levels of 1.55-39.0 p.p.m. averaging 14.0 ± 13.6 p.p.m. $(1\sigma; n = 10)$. These low concentrations reflect the lead-poor nature of ophiolitic volcanogenic sulphide deposits in contrast to Kuroko volcanogenic deposits which typically contain ~1% Pb, and are actually lower than lead concentrations of 115.0 ± 56.7 p.p.m. $(1\sigma; n=18)$ determined by isotope dilution for Fe-Mn hydroxyoxide metalliferous sediments associated with ophiolitic rocks in Cyprus, Syria and The Sultanate of Oman11. An independently determined set of ratios for the Skouriotissa deposit fall satisfactorily within the above ranges with corresponding values of 18.476, 15.571 and 38.405 (ref. 9). On ²⁰⁸Pb/²⁰⁴Pb against ²⁰⁶Pb/²⁰⁴Pb and ²⁰⁷Pb/²⁰⁴Pb against ²⁰⁶Pb/²⁰⁴Pb diagrams (Fig. 2), the ratios for the ophiolitic sulphide deposits in Cyprus define trends extending from near the mid-ocean ridge basalt fields (such as Alestos) to within the seawater fields defined by analysis of the Pb isotopic composi-tion of manganese nodules^{12,13} (such as Mathiati). Values for three of the deposits (Skouriotissa, Peristerka and Limni) cluster in an intermediate position, whereas two sets of determinations for Mousoulos have the highest ²⁰⁶Pb/²⁰⁴Pb ratios but have slightly lower ²⁰⁷Pb/²⁰⁴Pb and ²⁰⁸Pb/²⁰⁴Pb ratios than the seawater fields. The ranges enclose the values for the epidote-sulphide veined metadolerite dyke sample (CY/75/71; no. 7 in Fig. 2), which has already been noted as possibly Pb isotope contaminated, and are also surprisingly similar to the Pb isotope ranges for Fe-Mn hydroxyoxide sediments (umbers) associated with the ophiolitic rocks of Cyprus and the Baër-Bassit area in Syria¹¹. These oxidized metalliferous sediments are also thought to have formed as chemical precipitates from submarine hot springs. As the Pb isotope ratios for the sulphides occupy positions intermediate between the mid-ocean ridge basalt fields, which also contain values for the ophiolitic mafic rocks in Cyprus, and the seawater fields, the sulphide deposit lead apparently does contain a basaltic component, as expected, but the lead is actually a mixture which also contains lead derived from seawater.

The isotopic evidence for mixed lead in the ophiolitic sulphide deposits of Cyprus differs from data recently obtained for sulphide samples from 21°N on the East Pacific Rise ^{14,15}. For example, Vidal and Clauer ¹⁴ report ²⁰⁶Pb/²⁰⁴Pb, ²⁰⁷Pb/²⁰⁴Pb and ²⁰⁸Pb/²⁰⁴Pb ratios of ~18.48, ~15.49 and ~37.90. These values fall well within the MORB Pb isotope fields (Fig. 2) and correspond closely with the averages of the Pb isotopic

Fig. 1 Locations of the volcanogenic sulphide ore deposits in the ophiolitic rocks of the Troodos Massif, Cyprus, for which Pb isotope ratios have been determined in this study and by Doe and Zartman (Skouriotissa)⁹.

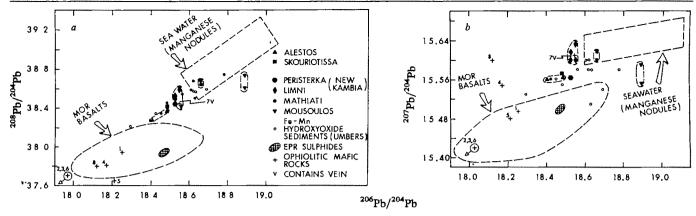

Fig. 2 Pb isotope ratios for volcanogenic sulphide ore deposits in the Troodos Complex, Cyprus, plotted together with ratios for a variety of variably hydrothermally metamorphosed mafic ophiolitic rocks from Cyprus, Fe-Mn hydroxyoxide rich chemical sediments (umbers) from Cyprus and Syria¹¹, general fields for mid-ocean ridge basalts¹⁰, general fields for seawater obtained by Pb isotopic analysis of manganese nodules^{12,13}, and sulphides from 21°N on the East Pacific Rise¹⁴. The numerals near the symbols for the ophiolitic mafic rocks refer to the samples listed in Table 1.

compositions of the associated basaltic rocks¹⁴. However, Fig. 2 shows that the lead isotope ratios for particular deposits in Cyprus seem to have restricted compositional ranges. In fact, the differences between ratios for Alestos and Mousoulos, both of which are in Cyprus, are actually greater than the differences between Alestos and the EPR 21°N samples. These sulphide deposit fields presumably, therefore, reflect a combination of the local lead isotope and mixing characteristics of each individual ore-forming geothermal system. The influence of source region is well shown by the more radiogenic Pb in the Kuroko volcanic sulphide ore deposits of Japan 16. 206 Pb/204 Pb, ²⁰⁷Pb/²⁰⁴Pb and ²⁰⁸Pb/²⁰⁴Pb ratios for galenas from 10 deposits of 18.42-18.62, 15.55-15.72 and 38.51-39.14 are interpreted to reflect variable lead derivation from Miocene volcanics and Palaeozoic basement¹⁶

One explanation of the differences in the Pb isotopic compositions of the EPR and Cyprus sulphides relates the facts that the EPR deposits are young and small. Hence, they are relatively enriched in unradiogenic leachable basaltic lead. The Cyprus deposits on the other hand, represent a completed process with a higher integrated water: rock ratio. The basaltic lead leached initially may have been diluted by more radiogenic seawater lead added subsequently.

We conclude that: (1) The Pb isotopic composition of the ophiolitic mafic rocks of the Troodos Complex is comparable with that of mid-ocean ridge basalts, but extends to such an unradiogenic combination of ²⁰⁶Pb/²⁰⁴Pb, ²⁰⁷Pb/²⁰⁴Pb and ²⁰⁸Pb/²⁰⁴Pb ratios as 16.620, 15.401 and 36.511 (T74). (2) The hypothesis of metal derivation by leaching of ophiolitic mafic rocks to form the volcanogenic sulphide ore deposits of Cyprus has some support. (3) The lead is, in fact, a mixture and seems to contain a variable component derived from seawater as well as a basaltic component. This observation differs from observations on recent sulphides from the East Pacific Rise, 21°N (refs 14,15). (4) Pb mixing probably occurred during convection within oceanic crust and not during discharge, as most of the samples examined were deliberately obtained from stockworks which were originally located at variable depths below the ocean floor. Data for a metadolerite sample containing originally dissolved Pb in a hydrothermal epidote-sulphide vein (CY/75/71) are consistent with this suggestion. (5) Lead in conformable sulphide deposits which has been used to construct lead isotope evolution curves (see refs 17,18) need not be exclusively of mantle derivation even when the associated igneous rocks are dominantly basaltic in composition as in the Troodos ophiolitic complex. Contamination by seawater may account for some of the scatter observed in detailed examinations of such conformable deposits (see ref. 19). The Pb isotope scatter is small, however, compared with the overall Pb isotope evolutionary range.

Temporal changes in the inorganic carbon system of the southeastern Bering Sea during spring 1980

L. A. Codispoti*, G. E. Friederich*, R. L. Iverson† & D. W. Hood‡

Previous studies of the inorganic carbon system in the southeastern Bering Sea1 demonstrated the occurrence of extremely low partial pressures of carbon dioxide (p_{CO_2}) and depressed total carbon dioxide concentrations (\(\Sigma CO_2\)) during late spring. To test the hypothesis that these conditions develop

during the spring phytoplankton bloom, and to provide biological production data that would be independent of the carbon-14 technique², we monitored the inorganic system in this region

intensively during spring 1980. We demonstrate here that there is a clear relationship between the changes in the inorganic carbon system and the spring phytoplankton bloom. Initially (March-early April), $p_{\rm CO_2}$ values in the surface waters were near or above the mean atmospheric content of 339 p.p.m., and $\Sigma {\rm CO_2}$ concentrations were ~2 mmol l⁻¹. By the end of the bloom, these variables were sometimes below 125 p.p.m. and 1.75 mmol l⁻¹ respectively, and the changes were correlated with nutrient decreases and dissolved oxygen and chlorophyll increases. At a mid-shelf station, it was possible to calculate net community organic carbon production from our data. The average rate between 23 April and 23 May was 3.6 g C m⁻² day⁻¹, in fair agreement with carbon-14-based primary production estimates.

Our p_{CO_2} data were taken continuously by sampling an air stream with an intake located near the T. G. Thompson's bow and a water stream taken from a depth of 3 m. The water stream was passed through an equilibrator3, and both the air and equilibrator gases were dried before analysis with a Beckman 315B IR analyser. Standards consisted of mixtures of CO2 and artificial air. Water stream results were corrected for a temperature rise (~0.5 °C) between the sea chest and the equilibrator and for an effect that arises when dissolved oxygen partial pressures are different than atmospheric. The p_{∞_2} data shown in Fig. 2 are for moist air. We determined ΣCO₂ (CO₂+ $H_2CO_3 + HCO_3^- + CO_3^{2-}$) by stripping acidified samples with nitrogen and drying the evolved gas before determination with a Beckman 215B IR analyser standardized with sodium carbonate solutions. Carbon-14 primary productivity rates were obtained from 8 h incubations in a deck incubator about 1.5 °C warmer than ambient surface water. Daily versus incubation period light observations were used to extrapolate daily rates from the incubation period results. The rest of our methods are described elsewhere4.

Figure 1 shows the PROBES (processes and resources of the Bering Sea shelf) line and the location of three quasi-stationary fronts that are normal features^{4,5,6}. Although tidal flows are substantial, mean flows in the PROBES region are only $\sim 1-5~\rm cm~s^{-1}$. There is evidence⁵ to suggest that the mean flow in the region between the middle and inner fronts is 1 cm s⁻¹, making this a favourable region for inferring biological rates from our $p_{\rm CO_2}$ and $\Sigma {\rm CO_2}$ time series.

Figure 2 shows the temporal evolution of the surface $p_{\rm CO_2}$ regime along the PROBES line in relation to the mean atmospheric value. Initial and final nitrate values are also indicated. These values do not show the presence of the middle front which is confined to the lower half of the water column⁶.

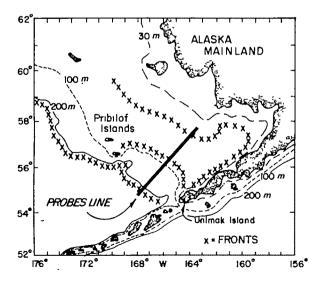

Fig. 1 Location chart showing the approximate position of the fronts that are present in the Bering Sea during the biologically active season, and the position of the main PROBES line.

As atmospheric exchange, vertical mixing, warming of surface waters as spring progressed and precipitation of calcium carbonate would all act to increase p_{CO_2} , the major factor causing the undersaturations seems to be the biological production of organic carbon. This hypothesis is supported by the nitrate data (Fig. 2) and also by the temporal changes in dissolved oxygen and chlorophyll. Initial (late March-early April) dissolved oxygen saturations in the surface waters were near 100%, but they rose as the bloom progressed. On the PROBES line, the maximum saturation value of 141% coincided with the minimum p_{CO_2} value of 120 p.p.m. (position 15 in Fig. 2, 16-17 March). Sometimes, maximum oxygen saturations occurred before minimum p_{CO_2} values. These situations might be expected because of the higher rate of O_2 exchange across the sea surface.

Initial chlorophyll values were generally less than $1 \mu g l^{-1}$ and never more than $1.5 \mu g l^{-1}$, but during the bloom, values in excess of $30 \mu g l^{-1}$ were encountered. Maximum chlorophyll values also occurred before minimum p_{CO_2} values in some cases. This is not surprising as the net productivity rate required to exceed our estimated atmospheric carbon dioxide invasion rates ($\sim 0.7 \text{ g C m}^{-2} \text{ day}^{-1}$, see below) is low in comparison with the maximum production rates.

Although biological production had the greatest effect on the p_{CO_2} values, physical processes also had observable effects. For example, the temporary reversal of the decreasing pw_{CO_2} trend at positions 11 and 12 on 22–23 April occurred during a period of enhanced vertical mixing.

As the p_{CO2} decreases (Fig. 2) seem to arise mainly from biological fixation of carbon, they should provide some insight into the timing of the spring bloom across the PROBES line. They suggest that some net productivity had occurred in the inner frontal region before our first observations. However, the first large p_{CO2} undersaturations occurred in or near the middle front and the bloom appears to have ended here and at position 15 first. By the end of our observational period (early June), the bloom appeared to be over everywhere, except for portions of the outer shelf and adjoining basin.

Some idea of the temporal variability in ΣCO_2 is given in Fig. 3. These changes, when combined with other data, allow the net community production rates to be estimated. We selected PROBES line position 12 for doing this because it is located in the region of weak mean currents mentioned above, and because we can compare the results with the relatively abundant carbon-14-based primary production measurements at this location. Salinity gradients in this region were weak, and using values that were normalized for salinity would not have changed the results. As the chemical results of biological production can be distributed by vertical mixing and advection, ΣCO_2 values were integrated over the total water column depth.

The interpretation of the changes in ΣCO_2 at position 12 is complicated by the existence of an anomalous station with high subsurface ΣCO₂ concentrations on 16 May. Examination of the temperature and nutrient distributions suggests that this was a transient introduced and removed by advection, but it significantly affects estimates of the ΣCO₂ removals arising from biological production. Regressions of $\Sigma CO_2 m^{-2}$ against time were 3.40 g C m⁻² day⁻¹ ($r^2 = 0.81$) with this value included and 4.32 g C m⁻² day⁻¹ ($r^2 = 0.94$) without it for the 23 April-23 May period. We believe that the latter regression is a better estimate of the change in ΣCO₂ concentrations at position 12 during this portion of the spring bloom as it minimizes random errors without being affected by the advective transient. That this transient influenced only a small portion of the shelf is suggested by similar regressions for the region between positions 11 and 13. Regressions with this value included and deleted gave rates of 4.12 g C m^{-2} day⁻¹ $(r^2 = 0.97)$ and $3.94 \text{ g C m}^{-2} \text{ day}^{-1} (r^2 = 0.97) \text{ respectively.}$

The above values have to be adjusted for the effects of mixing and advection, but only horizontal processes have to be considered as we are employing vertically integrated values. The existing transport models^{6,8} demand that a transient such as the

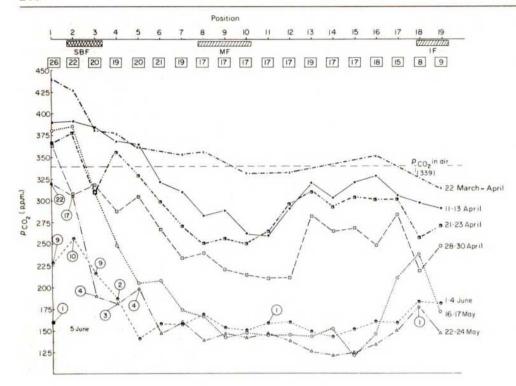

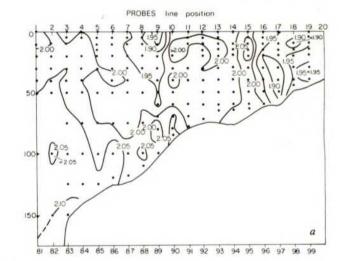

Fig. 2 The temporal evolution of p_{CO2} plotted against the mean atmospheric p_{CO_2} value along the main PROBES line during our 1980 experiment. The approximate locations of the fronts are indicated by the hatched boxes, and initial nitrate concentrations at the surface are indicated in the squares. Surface nitrate concentrations between 22 May and 5 June are shown in circles except for those cases where concentrations were less than 1 µg-atom 1-1. For clarity, partial lines taken on 2-5 and 6-9 May have not been included. Inclusion of these data would not have changed the general trends, but the number of temporary reversals in the generally decreasing trend would have increased. The pcO2 values are for moist air. On a dry air basis, the mean atmospheric value would be 341 p.p.m.

one observed at position 12 be averaged out over sufficiently long spatial or temporal domains, and it is not possible to do this using only the data for position 12. Hence, we used the position 11-13 space for this calculation (with the transient included). The above models suggest that longshore transport is insignificant, a conclusion that agrees with the longshore ΣCO₂ gradients that we observed. They also parametrically include mixing and advection in a cross-shelf diffusion coefficient which the most recent study suggests is 1× 106 cm2 s-1 in this domain (L.K. Coachman, personal communication). Applying this value to the appropriate gradients gives a diffusive supply of 0.14 g C m⁻² day⁻¹. Combining this value with the companion result from the regression analysis gives a total rate of 4.3 g C m⁻² day⁻¹. To test the strength of this calculation, we examined every possible combination of regression values and diffusive transports for position 12 only and for the position 11-13 region using calculations with and without the transient. This procedure had little effect on the answer for the position 11-13 region, the maximum difference being $0.3 \text{ g C m}^{-2} \text{ day}^{-1}$. For position 12 only, where it may not be appropriate to calculate the diffusive supply with the available model, the values ranged from 3.21 to 4.86 g C m⁻² day-1

With the appropriate constants and our temperature, salinity, p_{CO_2} and ΣCO_2 data, we calculated that approximately one-third of this decrease was due to the precipitation of calcium carbonate. This value seems reasonable, and if it applies to the entire water column, the decrease arising from the production of organic matter is 2.9 g C m⁻² day (based on our best estimate of 4.3 g C m⁻² day) for the total decrease).

A correction also has to be made for CO_2 invasion from the atmosphere. This was done by using the measured p_{CO_2} gradients across the air–sea interface and the 'piston velocity' concept^{7,10}. Literature values¹¹ were used to convert p_{CO_2} values into concentrations, and the average wind speed observed during the interval spanned by each gradient observation was used to obtain the appropriate 'piston velocity'. The average timeweighted invasion rate was $0.7 \text{ g C m}^{-2} \text{ day}^{-1}$ for both position 12 and the position 11–13 region. The net community organic carbon production rate arising from the above analysis is $3.6 \text{ g C m}^{-2} \text{ day}^{-1}$.

Seven carbon-14-based primary production rate determinations made at position 12 (between 20 April and 26 May) give

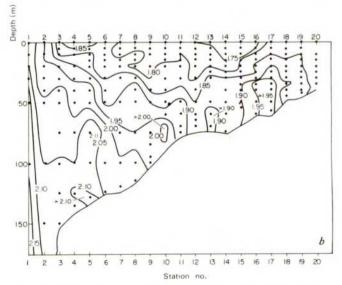

Fig. 3 Total carbon dioxide (in mmol l⁻¹) distribution on the PROBES line, 21-23 April (a) and 22-24 May (b).

a time-weighted average rate of 3.5 g C m⁻² day⁻¹ for the 23 April-23 May period. One would expect that the rate based on the changes in the inorganic carbon system should be smaller than the carbon-14-based rate. The difference between primary and community production could be small in the prevailing conditions, however, because the phytoplankton community at position 12 was composed of diatom species which did not seem to be significantly affected by herbivores that were present in low numbers. Although the carbon-14 method does not always compare favourably with other methods¹²⁻¹⁴, it does give reasonable estimates of particulate organic carbon production for some diatom populations¹² in eutrophic conditions^{15,16}. This discrepancy could also arise from errors in our comparison. Large errors in the choice of a diffusion coefficient, in the air-sea gas exchange, or in the amount of calcium carbonate precipitation would be required to alter our net community production rate by 1 g C m⁻² day⁻¹, but our test of our calculation suggests that factors such as insufficient resolution of temporal and

spatial gradients could cause errors of this magnitude. An examination of the carbon-14 results suggests that this value may also be a partial function of sampling density. Because differences of the order of 1 g C m⁻² day⁻¹ could arise from errors associated with sampling density, there is no firm evidence to suggest that the carbon-14 method itself suffered from large errors in the conditions of our experiments. However, it is possible that this method estimated net community production more accurately than it estimated primary production.

We thank our colleagues in the PROBES program for data and comments, and G. Grunseich, A. Hafferty and D. Lowman for assistance. Financial support was provided by the NSF's Division of Polar Programs. We particularly thank Dr J. J. Kelly for advice and some necessary equipment. Variability in the abundance of animal and plant species

R. M. Anderson, D. M. Gordon*, M. J. Crawley & M. P. Hassell

Department of Pure and Applied Biology, Imperial College, London University, London SW7 2BB, UK

* Department of Zoology, King's College, London University, London WC2R 2LS, UK

A striking and consistent observation in ecology is that variability in population abundance of a species and average population density are related in both space and time1,2. Taylor and his colleagues have shown that this relationship between variance (V) and mean (M) conforms well to a simple power law for a very wide range of animal and plant species, with the logarithms of sample variance and average sample density following a linear relationship¹⁻³ ($V = \hat{a}M^{\delta}$ where \hat{a} and \hat{b} are constants). They suggest that the slope of this line, \hat{b} , which generally falls within the range 1 to 2, is a species-specific characteristic reflecting the balance between the opposing behavioural tendencies to aggregate within, and migrate from, centres of population density4. Taylor and co-workers1-6 have stressed that migration between patches is rarely a random process, on the evidence of the observed 'density-dependent' relationships between the degree of dispersion (the variance to mean ratio, V/M and mean abundance per patch). We show here that the relationship between variability and average abundance can be a simple, and inevitable, consequence of chance demographic events in the dynamics of population growth and decline. The precise form of these relationships is determined by the relative magnitude of the various rate processes which govern the dynamics of population change (the birth, death, immigration and emigration rates), and by the degree of spatial and temporal heterogeneity. We do not need to invoke any complex behavioural mechanisms to explain observed patterns.

Random or chance events play a major role in the population dynamics of all organisms. In any given time interval there is

only a certain probability that an organism will die or give birth, or that an immigrant will arrive or emigrant leave, partly as a consequence of the intrinsically discrete structure of populations7. The significance of such demographic stochasticity7-9 to observed patterns of variability and abundance can be examined using simple markovian population models. We begin by considering the temporal dynamics of a population in a defined space subject to constant rates of birth, death, emigration and immigration (denoted respectively by λ , μ , γ and δ) which are independent of population density (λ , μ and γ are defined as per capita rates while δ is defined per population). A continuous time stochastic model predicts that the probability distribution of population size at any point in time is overdispersed and negative binomial in form $^{10-12}$, where at time t (the initial population size N_0 at time t = 0 is taken to be zero), the mean M(t), and variance V(t), are given by

$$M(t) = \frac{\delta}{r} [e^{rt} + 1] \tag{1}$$

$$V(t) = M(t) \left[1 + \frac{\lambda}{\delta} M(t) \right]$$
 (2)

The intrinsic growth rate of the population, r, is defined as $r = (\lambda - \mu - \gamma)$. The variance to mean ratio, V(t)/M(t), is greater than unity and tends to rise linearly as average abundance increases (density dependent in the terminology of Taylor^{1,4}), with slope λ/δ . At low population densities, when the value of δ is large in relation to λ (often the case during the early stages of habitat colonization), the variance will be approximately equal to the mean. As average density rises, the log-log plot of variance against mean will become linear, with a maximum slope of 2 (Fig. 1a). The slope of the best-fit linear equation will therefore lie between 1 and 2 depending on the range of densities sampled and the relative magnitudes of the parameters λ and δ (Fig. 1a). Note that the vast majority of observed relationships also have slopes lying between 1 and 2

Simple stochastic models of pure population processes show how different patterns of dispersion can be generated. Birth rates, for example, generate over-dispersion, immigration rates generate randomness, while death and emigration rates tend create under-dispersion^{8,13,14}. Observed patterns

dispersion therefore depend on the dynamic balance between these opposing forces.

Stochastic models can also aid in the interpretation of spatial patterns of variability. For example, assume that a habitat is divided into P patches where the immigration rate per patch, δ , is random but dependent on the net rate of emigration from all other patches. When all other rates are constant and independent

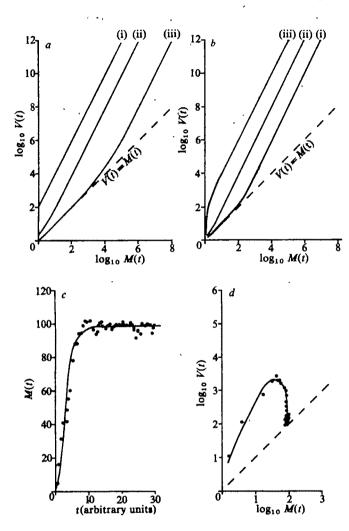

Fig. 1 a, The relationship between the logarithms of the variance in population size at time t, V(t), and mean population size, M(t), predicted by equations (1) and (2) in the text. The three solid lines denote the relationship for different birth (λ) and immigration (δ) rates: line (i), $\lambda/\delta = 0.001$; line (ii), $\lambda/\delta = 1$; line (iii), $\lambda/\delta = 100$. The probability distribution of population size is negative binomial in form parameter k (which varies inversely with the degree of dispersion) equal to δ/λ . The dashed line denotes the relationship for a Poisson distribution where V(t) = M(t), b, Similar to a but representing the relationship predicted by the spatial model defined in equations (3) and (4). The three solid lines denote the relationship for different values of the parameter combination C = [A+B]/[A-B] (see text): line (i), C = 0.01; line (ii), C = 1.0; line (iii), C = 100. Initial population size N_0 was set at 1. The dashed line is as defined for a. c, d Present the results of a Monte Carlo simulation experiment of the growth of a population subject to constant rates of birth, immigration and emigration, and a density-dependent rate of mortality $\mu(N)$, where $\mu(N) = \mu + \alpha N$ (N represents population density). The experiments were carried out along standard lines^{13,14} where the equivalent deterministic differential equation for the temporal dynamics of N is of the form $dN/dt = \delta + (\lambda - \gamma)N - (\mu + \alpha N)N$. a Records changes in the mean population size, M(t), through time, estimated from 25 replicate simulations. The solid dots are experimental results while the solid line is fitted by eye to denote the general temporal trend. In b the logarithms of the variances in population size (estimated from the replicate simulations) at time t, V(t), are plotted against the logarithms of means M(t). The dots are experimental results while the solid line is fitted by eye. The dashed line denotes the Poisson prediction where V(t) = M(t). Note that the relationship between $\log_{10} V(t)$ and $\log_{10} M(t)$ is curvilinear, where the degree of dispersion rises to a peak and then declines at high average densities: The parameter values used in the simulations were $\delta = 0.5$, $\lambda = 7.5$, $\mu = 2.0$, $\gamma = 0.5$ and $\alpha = 0.05$ (all defined per time unit).

dent of population density, the mean abundance per patch M(t), and the variance in density between patches, V(t), are now approximately given by

$$M(t) = N_0 \exp[(A-B)t]$$
 (3)

$$V(t) = \frac{(A+B)}{(A-B)}M(t)\left[\frac{M(t)}{N_0} - 1\right] \qquad (4)$$

The parameters A and B are defined for notational convenienc as $A = \delta P \gamma / (b + \delta P) + \lambda$ and $B = (\mu + \gamma)$; N_0 is the total popular tion size in the habitat at time t=0 and b is the per capit death rate of the migrating organisms. It is assumed in the derivation of equations (3) and (4) that there is a risk associate with migration such that $b \gg \mu$ and that in any given pate population growth is a simple birth (at a rate A)—death (at rate B) process where a component $(\delta P \gamma/(b + \delta P))$ of the birt rate is the arrival of immigrants from the remaining patches^{8,1} The probability distribution of abundance per patch is overdipersed in form (similar, but not identical, to the negative binomial distribution) where V/M increases linearly with mea abundance, with a slope of $(A+B)/[N_0(A-B)]$. The log-lc plot of variance against mean is again approximately linea with a slope in general lying between 1 and 2, depending o the range of densities sampled and the values of the populatic parameters (Fig. 1b). (At very low average densities the slot may even be greater than 2.)

This result does not support Taylor's view (see above) the such patterns are likely to be due to nonrandom migratio because our simple model assumes migration to be a randor process between patches. Similar conclusions have also bee reached by Hanski¹⁵.

We have so far assumed that the rates of population chang are independent of density; of course, this is rarely the case natural habitats. Density dependence, whether acting on the birth, death, emigration or immigration rates (or any combination) tion of these), serves to regulate population abundance in given habitat to a typical equilibrium K (refs 16-18). Mar factors may account for such density dependence, includir complex behavioural processes (which often influence emigra tion and/or immigration rates). When a population is at or ne K, density-dependent processes (which reduce birth ar immigration rates, or increase death and emigration rates, density rises) tend to generate underdispersion, as illustrate by the Monte Carlo simulation experiments recorded in Fi 1c, d. The pattern of dispersion changes from random whe the habitat is being colonized, to overdispersed as the popul tion grows exponentially, to random or underdispersed as th population approaches K. A curvilinear relationship betwee $\log V$ and $\log M$ is thus produced, as shown in Fig. 1d.

Patterns of this form are seldom recorded even for 'I strategist'¹⁹ species living in relatively stable habitats. Or example is provided by the vole, *Microtis pennsylvanicus*, in i grassland habitat, where the degree of dispersion changes from overdispersed to underdispersed as population densitincreases²⁰. In the case of 'r-strategists'¹⁹ we are unaware any examples similar to that in Fig. 1d. Thus, contrary to the predictions of our model, there is little evidence that the degree of dispersion declines at high population densities¹⁻⁴.

The models examined so far, however, fail to take accound a crucial feature of almost all natural habitats, namely environmental heterogeneity. Because of fluctuating environmental conditions, both in space and time, population rate parameters are in reality random variables, not constants 21,2 . Environmental stochasticity acts to compound the underlying variability created by demographic events, and has a centrarole in determining observed patterns of population dispersion. To illustrate this, we consider a model in which the carrying capacity, K, of each patch is a random variable (normal distributed with mean K and variance s_K^2). Monte, Carls simulation studies reveal that log-log plots of the variance abundance between patches against the mean population density will tend to be approximately linear over all densities

with a slope lying between 1 and 2, provided the habitat is moderately heterogeneous. There is little evidence of a decline in the degree of dispersion at high average densities, despite the fact that density-dependent processes are regulating overall abundance (Fig. 3a, b, e, f). When sampling is restricted to patches where the density is near to the average carrying capacity, \vec{K} , then the slope of the log-log plot of variance against mean ranges from close to, or less than, unity if the habitat is relatively homogeneous, to greater than 2 if the habitat is highly heterogeneous (Fig. 3). Such slopes greater than 2 have occasionally been observed in studies of spatial and temporal trends in the pattern of population dispersion (Fig. 2).

The range of values over which the slope can vary is small (roughly 0.5-2.5, Fig. 2), its precise value being critically dependent on sample size, the range of densities over which samples are collected and the degree of environmental heterogeneity at the time and place of sampling (Fig. 3). For a fixed set of parameter values, for example, the slope may vary greatly between one simulation and another even when sample size is large. The slope will tend, on average, to be determined by the values of the population parameters that control the growth of

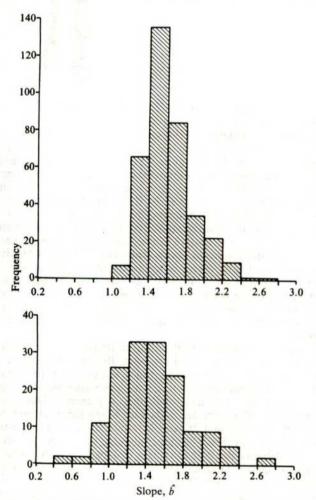

Fig. 2 Frequency distributions of the slopes of the best-fit linear model to the logarithms of sample variance and mean density estimated from a wide range of ecological data. The linear model is of the form $\log_{10}V = \log_{10}a + b \log_{10}M$ where b is the slope and $\log_{10}a$ the intercept b. Temporal trends. This figure denotes the frequency distribution of slopes b estimated from samples of the abundances of various moth and aphid species collected over a period of at least b yr at sites in Great Britain and mainland Europe (data analysed by Taylor and Woiwood²). The means and variances in population abundance from which the slopes were estimated were calculated from samples taken at one site over a period of 1 yr. The frequency distribution represents slopes for 360 species. b, Spatial trends. Similar to a but representing the frequency distribution of slopes estimated from samples of the abundances of species ranging from plants, through protozoa, to mammals, taken at one point in time at different spatial sampling sites (data analysed by Taylor, Woiwood and Perry¹). The frequency distribution records slopes for 155 species.

a given species, but these often vary on a regular seasonal basis. It may be possible, however, to discern general trends in the sense that species with high birth rates that live in unstable heterogeneous habitats (r-strategists) will tend to have steeper slopes than those that have low birth rates and live in stable

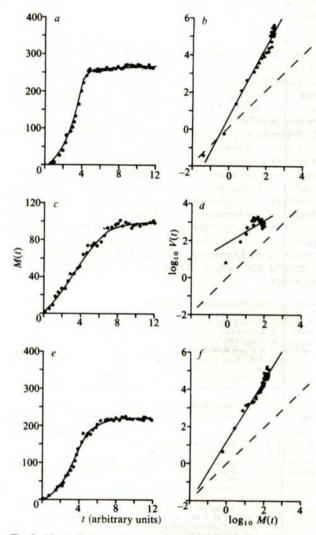

Fig. 3 Monte Carlo simulation studies of the impact of environmental stochasticity on population growth and the degree of dispersion. The results presented represent three experiments using a model in which the carrying capacity of the patches within a habitat is assumed to be a random variable. The model is identical to that described in the Fig. 1 legend to (c, d) except that the density-dependent coefficient, α , was assumed to be normally distributed with mean $\bar{\alpha}$ and variance s_{α}^2 . The simulations were carried out along standard lines ^{13,14} except that for each replicate of population growth within a patch a pseudorandom number was used to select a value for α and hence determine the carrying capacity, K, of the patch. K was assumed to be constant through time for any given patch. a, b Portray the results of one experiment in which the parameter values were set at $\delta = 0.5$, $\lambda = 7.5$, $\mu = 2.0, \ \gamma = 0.4, \ \bar{\alpha} = 0.05, \ s_{\alpha}^2$ $\mu = 2.0$, $\gamma = 0.4$, $\bar{\alpha} = 0.05$, $s_a^2 = 0.025$. a Records changes in the mean population density per patch, M(t), through time, of 25 patches. The solid dots denote experimental results while the solid line is fitted by eye. b Records the relationship between the logarithms of the variance in population size between patches at time t, V(t) (given that each patch has a different carrying capacity, K, where

$$K = [\lambda - (\gamma + \mu) + [(\gamma + \mu - \lambda)^2 + 4\alpha\delta]^{1/2}]/(2\alpha))$$

and the mean population size per patch, M(t) (sample size = 25). The solid dots denote experimental results while the solid line represents the best-fit linear model of the form $\log_{10}V(t) = \hat{a} + \hat{b} \log_{10}M(t)$, where the constants have the values $\hat{a} = 0.76$, $\hat{b} = 1.91$. The dashed lines denote the Poisson prediction where V(t) = M(t). c, d Are similar to a and b except that in the simulation experiments (25 replicates) the variance of the random variable α is set at $s_a^2 = 0.0125$ to represent a fairly homogeneous habitat (in the experiments recorded in a and b the larger value of s_a^2 implies a more heterogeneous habitat). In d the parameters of the best-fit linear model are $\hat{a} = 1.87$, $\hat{b} = 0.58$. e, f Are again similar to a and b except that the parameters λ and μ were changed to $\lambda = 10.0$ and $\mu = 5.0$. The degree of environmental heterogeneity was the same as that for a and b. In f the parameters of the best-fit linear model are $\hat{a} = 1.11$, $\hat{b} = 1.69$.

and relatively homogeneous habitats (K-strategists). Some support for this conjecture is provided by the available empirical

The patterns of dispersion generated by simple models of population growth lead us to believe that observed relationships between variability in population abundance and average density, highlighted by the work of Taylor³, are in general a simple and inevitable consequence of demographic and environmental stochasticity. It is not necessary to invoke explanations based on the behavioural tendencies of species to aggregate and migrate4 in order to understand the trends that have been observed in natural habitats. Indeed, in a spatially uniform world, and in the complete absence of demographic stochasticity, such tendencies will not generate power law relationships between population variability (V) and average abundance (M). When density-dependent factors are of limited significance (r-strategists) demographic stochasticity alone is sufficient to account for the approximately linear relationship between the logarithms of variance and mean abundance and for the slopes of such relationships lying on average between 1 and 2 (Fig. 2). In the presence of strong density dependence (K-strategists), a degree of environmental heterogeneity (either in space or time, or both) will ensure that such relationships remain approximately linear over all average densities (Fig. 3)

A possible case of hypervitaminosis A in *Homo erectus*

A. Walker*, M. R. Zimmerman† & R. E. F. Leakey‡

Following an initial discovery by Bw. K. Kimeu in 1973, sleving operations have recovered the most complete Homo erectus skeleton so far known (Fig. 1) from the Upper Member of the Koobi Fora Formation in Area 103, Koobi Fora, East Lake Turkana in Kenya^{1,2}. The partial skeleton shows pathological changes consistent with chronic hypervitaminosis A. We attribute this disorder to the high dietary intake of animal liver, most probably that of carnivores, during a period when the dietary habits of Homo erectus were changing.

The geological age of the specimen (KNM-ER 1808) is constrained by the ages of the overlying Koobi Fora Tuff and the top of the underlying Olduvai Event. The Koobi Fora Tuff is actually a complex body of tuff, tuffaceous sediment and sediment, as are the Okote and Middle Ileret Tuffs. Cerling and Brown (personal communication) have established that some parts of each of these tuff complexes can be correlated. Fitch and Miller³ reported K/Ar dates on sanidine separates from the Koobi Fora Tuff ranging from 0.53 to 4.44 Myr, dates on the Okote tuff ranging from 0.87 to 1.70 Myr, and a date of 1.48 Myr for the Middle Ileret Tuff. Their preferred ages for the Koobi Fora and Okote Tuffs are 1.57 and 1.56 Myr respectively. Curtis (personal communication) has dated the Okote Tuff at 1.48, 1.46 and 1.44 Myr. Thus a reasonable younger limit on the age of the specimen is 1.5 Myr. The age of the top of the Olduvai Event is given as 1.76 Myr by MacDougall⁴, providing an older limit for the age of the specimen.

Fig. 1 Diagram showing the pre-

specimen KNM-ER 1808.

The precise position of the polarity transition is uncertain, but is known to lie at least 12 m below the specimen, and may lie much lower in the section. Since the specimen lies fairly close to the Koobi Fora Tuff, a reasonable estimate of its age is 1.6 ± 0.1 Myr. This adult individual is presumed female by comparison of innominate parts with KNM-ER 3228 (ref. 5) and Olduvai Hominid 28 (ref. 6), which are considered male and female respectively by modern human osteological criteria.

The appendicular skeleton shows striking pathology, consisting of subperiosteal diaphyseal deposit of coarse-woven bone. The new bone, 7.0 mm thick in places, thins towards the metaphyses. There is minimal endocranial involvement. Ground thin sections of the tibial shaft (Fig. 2) show pathology confined to the outermost cortex, which has given rise locally to new bone. The sharply demarcated, coarse-woven new bone contains enlarged, sub-spherical and randomly placed lacunae. There is no evidence of abnormal remodelling of the underlying bone. The dense mineralization of the specimen accounts for the fine histological preservation, but precludes satisfactory radiological examination.

Although a disease that no longer exists or has changed its manifestations can neither be diagnosed nor excluded, we suggest that KNM-ER 1808 had chronic hypervitaminosis A. Although the night blindness of vitamin A deficiency has been known since antiquity, the deleterious effects of excessive ingestion became known only much more recently. Early polar explorers reported the development of an acute toxic state on ingestion of polar bear, seal or husky dog liver^{7,8}. However, it was not until 1942 that Rodahl and Moore⁹ identified vitamin A as the toxic component of seal and polar bear liver.

Acute hypervitaminosis A, characterized by symptoms of peeling of the skin, vomiting and diarrhoea, headache and convulsions, may be fatal. The condition, now rarely seen in adults, is fairly common in infants after accidental ingestion or misguided parental enthusiasm¹⁰.

Chronic hypervitaminosis A is a considerably more subtle disease, which became recognized as a clinical entity only in the mid-twentieth century. Although the condition is fairly common in children¹¹⁻¹⁴, only 17 cases have been reported in adults since 1951^{7,11,15-22}.

Skeletal manifestations have been variable in these patients. Periosteal calcification of the long bones, well known in children²³, was detected in only 3 of the 17 adults^{7,17,18}. The only case biopsied⁷ showed thickened tibial periosteum with the formation of poorly calcified coarse-fibred new bone. All cases of hypervitaminosis A are probably associated with bone changes, although standard radiographic techniques are insensitive to early changes²⁴. Another case¹⁹, biopsied in the absence of radiological abnormalities, showed large osteocytic lacunae, focal hypermineralization and an increased rate of bone turnover. The enlarged lacunae are thought to be due to the osteocytes assuming an osteoclast-like function, accounting for the hypercalcaemia of hypervitaminosis A.

Bone changes are seen in adult experimental animals with administration of excess amounts of vitamin A^{25,26}. Rats fed large doses of vitamin A showed considerable periosteal bone deposition, with low density, cancellous-type new bone overlying the cortical bone²⁷. Large osteocytes, seen within confluent lacunae, matured rapidly, tending to produce osteolysis with partial breakdown of the bone matrix.

Other conditions causing abnormal calcification must be considered in a differential diagnosis. Hypervitaminosis D leads to hypercalcaemia and metastatic visceral calcification, with the bones becoming markedly osteoporotic. Cystic lesions of the bones ('brown tumours') are seen in hypoparathyroidism. Some modern cases of hypoparathyroidism have shown increased cortical density, but it is unlikely that a hominid living 1.6 Myr ago would have survived the associated tetany long enough to have developed skeletal changes. Fluorosis also produces osteosclerosis, but this is said to be due to both periosteal and endosteal bone formation. The histology is not well documented^{28,29}. Subperiosteal calcification in scurvy, usually metaphyseal rather than diaphyseal, is associated with cortical thinning and epiphyseal separation28. Infantile cortical hyperostosis involves the mandible and resorbs with ageing30. Generalized cortical hyperostosis (Van Buchem's disease) affects many parts of the skeleton, but shows endosteal thickening, especially in the skull³⁰. The periosteal bone deposition of osteomyelitis variolosa, associated with childhood smallpox, is most prominent near the joint capsule, with possible sequestration of the epiphysis³¹⁻³³. In syphilitic osteomyelitis, the skull is almost always involved; endosteal proliferation is usual, as are large destructive foci (gummas)^{30,31}. Hypertrophic osteoarthropathy is often associated with periosteal bone deposition, but the histology is that of normal cortical bone31

The most likely diagnosis is, therefore, hypervitaminosis A. If we are correct, how did this *Homo erectus* ingest such large doses of the vitamin?

In the Koobi Fora succession, the first record of the use of stone artefacts and their association with animal bones, presumably representing early hominid meals, antedates KNM-ER 1808 by some 200,000 yr. There was probably a major change in the diet of early humans, with a large increase in meat eating, at that period and it may have taken some time to learn which parts of which carcasses were poisonous. One hundred grammes of modern herbivore liver contain 44,000-50,000 IU of vitamin A, whereas 100 g of carnivore liver contain 1.3-1.8 × 10⁶ IU as carnivores derive and store large amounts of preformed vitamin from livers of their prey. The condition described above is

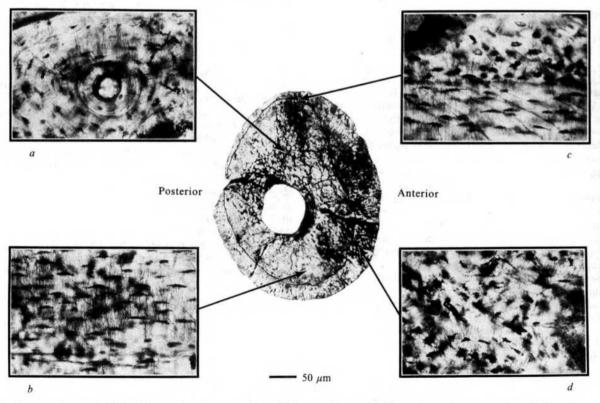

Fig. 2 Cross-section at midshaft of femur showing outer layer of abnormal bone and thin sections taken approximately from the positions shown. a, Normal osteon from deeper part of shaft. b, Outer lamellar bone showing normal, flattened osteocytic lacunae and canaliculi. c, Junction of normal lamellar and abnormal bone, showing sudden transition from normal lacunae to subspherical, disorganized lacunae with more randomly disposed canaliculi. d, Disorganized area typical of the abnormal bone.

unlikely to be due to ingestion of the easily masticated liver of a herbivore (there is no evidence of the use of fire at this time), but quite possibly to a diet containing carnivore liver. Interference behaviour of the type seen today between carnivore species³⁴ would be expected when early hominids began to compete directly with carnivores. Some of these interactions might have resulted in carnivores being killed and eaten by hominids.

Alternatively, or additionally, selection for tolerance to high levels of vitamin A may have been slow, with KNM-ER 1808 representing one individual who could not store vitamin A at high levels. This is unlikely, however, because normal human liver levels are within herbivore ranges³⁵. It is more likely that

β -Endorphin is processed differently in specific regions of rat pituitary and brain

S. Zakarian & D. G. Smyth

Laboratory of Peptide Chemistry, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK

Recent studies have shown that β -endorphin is found in the pituitary with two related peptides, the C-fragment (β -endorphin₁₋₂₇)^{1,2} and the des-histidine derivative of the C-fragment $(\beta$ -endorphin₁₋₂₆)³, and that each of these peptides (Fig. 1) occurs also in an α , N-acetyl form^{3,4}. The six peptides are derived from a single precursor by differential proteolytic cleavage and acetylation. The fact that different forms of β -endorphin predominate in different regions of the pituitary5,6 implies that there are region-specific differences in processing of the precursor. Because β -endorphin is known to occur widely in the brain^{7,8} as well as in the pituitary we have now investigated the distribution of the six peptides in selected regions of rat brain. We report here that, as in the pituitary, different regions of the brain contain strikingly different proportions of the six β endorphin-related peptides, apparently as a result of differential processing.

Dissected regions of rat pituitary (10 male Sprague-Dawley rats, 250 g) and of rat brain (30 rats), and also whole brain (5 rats), were extracted in acetone/HCl/water (40:1:5, v/v) and the soluble products fractionated by gel filtration on a Sephadex G75 column (70×1.5 cm) in 50% acetic acid. The elution position of the group of β -endorphin-related peptides was identified using ¹²⁵I-labelled bovine markers added to each homogenate. The marker peptides, isolated from ox pituitary, were β -endorphin, α , N-acetyl β -endorphin, the C'-fragment and α , N-acetyl C'-fragment. The endogenous β -endorphinrelated peptides, together with the markers, were resolved by chromatography on a sulphopropyl Sephadex C25 (pyridinium form) column (70×0.6 cm) in 50% acetic acid with a 0-1 M pyridine linear gradient (100 ml mixer) and located by radioimmunoassay using an antibody raised against β -endorphin¹⁰. The identity of four of the six peptides was finally confirmed by HPLC on a C₁₈ microbondapak column in 0.01 M hydrochloric acid with a 25-40% acetonitrile linear gradient (30 min)⁵. The elution positions of the immunoreactive peptides were compared with the positions of the corresponding bovine peptides in consecutive chromatograms. Each experiment was repeated several times (five times for regional distribution of the pituitary and two to six times for region of brain); only minor differences were observed in the patterns of distribution and the amounts of each peptide.

In rat pars intermedia six peptides having β -endorphin immunoreactivity were resolved (Fig. 2); four corresponded to the known marker peptides, β -endorphin₁₋₃₁ (VI), acetyl β endorphin₁₋₃₁ (V), β -endorphin₁₋₂₇ (IV) and acetyl β -endorphin₁₋₂₇ (II), and the remaining components (III and I), which were the principal peptides of the pars intermedia, had chromatographic properties corresponding to porcine β -endorphin₁₋₂₆ and its α , N-acetyl derivative. Thus in rat pars intermedia, β -endorphin is a minor component and the major β endorphin-related peptides are essentially inert as opiates. In contrast, the major peptide in the anterior pituitary with the approximate molecular size of β -endorphin eluted in the position of β -endorphin₁₋₃₁. Similar processing patterns have

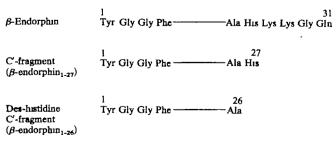

Fig. 1 β-Endorphin-related peptides identified in porcine pituitary. In the rat, valine replaces alanine at position 26 (ref. 11).

been found in other species, including pig^{3,5}, mouse, cat and guinea pig (S.Z. and D.G.S., unpublished results).

The six peptides identified in rat pituitary were shown to be present also in rat brain. Ion-exchange chromatography of the β -endorphin-related peptides extracted from whole brain (Fig. 3) indicated that the acetylated forms were relatively minor; the principal peptides were β -endorphin₁₋₃₁ and β -endorphin₁₋₂₆. Examination of the peptides extracted from regions of brain, however, revealed two contrasting processing patterns, one for the hypothalamus, midbrain and amygdala, and the other for the hippocampus, dorsal colliculae and brain stem. The hypothalamus contained predominantly the biologically potent form of β -endorphin and the midbrain and amygdala again contained β -endorphin but it was accompanied by β -endorphin₁₋₂₆ (Fig. 4a); in these regions there were negligible acetyl peptides. In contrast the hippocampus, dorsal colliculae and the brain stem also contained the α , N-acetyl forms of

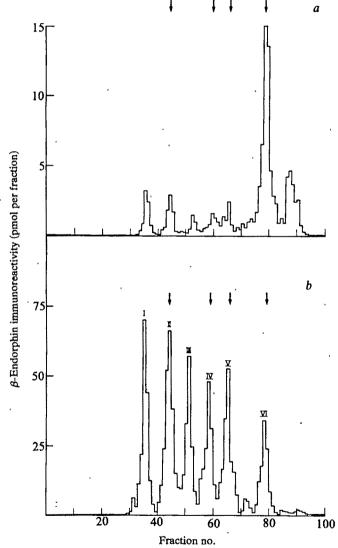

Fig. 2 Ion-exchange chromatography of β -endorphin-related peptides extracted from the anterior pituitary (a) and pars intermedia plus posterior pituitary (b) of the rat. The weights (in mg) of freshly dissected tissues were: anterior pituitary, 8.9 ± 1.2 ; pars intermedia, 1.1 ± 0.1 (mean \pm s.d. calculated from 20 rats). The elution positions of the radio-iodinated reference peptides $(\alpha, N$ -acetyl β -endorphin₁₋₂₇, β -endorphin₁₋₃₁), which exhibit slightly greater retention than the endogenous peptides, are indicated respectively from left to right by the arrows. α, N -acetyl β -endorphin₁₋₂₆ (peak I) and β -endorphin₁₋₂₆ (Peak III) chromatographed in positions not indicated by the marker peptides. The column conditions are described in the text. Fractions were 1.5 ml.

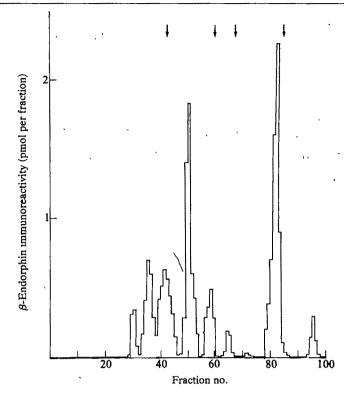

Fig. 3 Ion-exchange chromatography of β -endorphin-related peptides extracted from whole rat brain. The mean weight of intact brain was 1.83 ± 0.17 g (20 rats). The elution positions of the 125 I-labelled reference peptides $(\alpha,N$ -acetyl β -endorphin₁₋₂₇, β -endorphin₁₋₂₇, α,N -acetyl β -endorphin₁₋₃₁ and β -endorphin₁₋₃₁) are indicated from left to right by the arrows. α,N -acetyl β -endorphin₁₋₂₆ and β -endorphin₁₋₂₆ to not elute in positions indicated by the marker peptides. Note that the major peptides are β -endorphin₁₋₃₁ and β -endorphin₁₋₂₆. Fractions were 1.5 ml.

 β -endorphin₁₋₂₇ and β -endorphin₁₋₂₆; the NH₂ forms of the peptides were less significant (Fig. 4b).

These results point to the existence of differential processing mechanisms in various regions of rat brain, as is the case in different regions of the pituitary. In the anterior pituitary and hypothalamus, β -endorphin seems to be formed by the action of an enzyme that cleaves between lysylarginine and tyrosine (positions 39-41 of rat lipotropin¹¹). In the amygdala and midbrain, however, β-endorphin₁₋₂₆ is an additional component, which would seem to require the action of two further enzymes, an endopeptidase for cleavage at Lys-Lys-Gly (positions 68-70 of rat lipotropin) and a carboxypeptidase B-like enzyme for removal of C-terminal lysine and histidine. On the other hand, in the pars intermedia, hippocampus, dorsal colliculae and brain stem the most abundant peptides are derivatives of either β -endorphin₁₋₂₇ or β -endorphin₁₋₂₆ and they are largely present in the acetylated form. The elaboration of these peptides would seem to involve the action of at least four enzymes—the two endopeptidases, the carboxypeptidase B-like exopeptidase and an α , N-acetylating enzyme. Note that of the six peptides related to β -endorphin, β -endorphin alone possesses potent analgesic properties^{12,13} and the formation of any one of the other peptides is accompanied by almost complete loss of the analgesic activity3,14.

The secondary processing of β -endorphin may involve reactions that are time-dependent. In the brain, the processing could occur in the cell bodies where β -endorphin seems to be synthesized, during transport along axons, or during storage at the nerve terminals. Thus the peptides present in the different regions might reflect the duration of their exposure to specific processing enzymes. Indeed, the predominance of β -endorphin₁₋₂₆ and β -endorphin₁₋₂₇ rather than β -endorphin₁₋₃₁ in the brain stem, dorsal colliculae and hippocampus would be

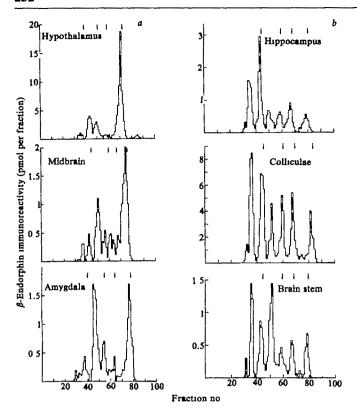

Fig. 4 Ion-exchange chromatography of β -endorphin-related peptides extracted from dissected regions of rat brain. The mean weights (in mg) of the freshly dissected tissues were: hypothalamus, 102 ± 18 ; midbrain, 131 ± 15 ; amygdala, 60 ± 19 ; hippocampus, 153 ± 22 ; dorsal colliculae, 127 ± 11 ; brain stem, 270 ± 30 (values calculated from 30 rats). The elution positions of the ¹²⁵I-labelled reference peptides (α, N-acetyl β-endorphin₁₋₂₇, β-endorphin₁₋₂₇, α , N-acetyl β -endorphin₁₋₃₁ and β -endorphin₁₋₃₁) are indicated from left to right by the arrows. Fractions were 1.6 ml. Note that the hypothalamus, midbrain and amygdala exhibit one pattern of processing (a) while the hippocampus, dorsal colliculae and brain stem exhibit another (b),

consistent with the concept that most of the secondary processing takes place distally from the hypothalamus, as it is only in the hypothalamus that cell bodies occur^{10,15}. On balance, however, the specific nature of the products formed in the different tissues, and the multiplicity of the enzymes necessary for their formation, suggests that distance from the site of biosynthesis is unlikely to be responsible for the organized distribution of peptides observed. The nature and amounts of the peptides present in each region are probably determined by the controlled action of specific enzymes located in those regions.

Insulin-like growth factor I stimulates growth in hypophysectomized rats

Eugen Schoenle*, Jürgen Zapf*, René E. Humbel† & E. Rudolf Froesch*

Although growth hormone stimulates the growth of hypophysectomized rats, it has long been proposed 1,2 that the effects are not direct but instead are mediated by the somatomedin peptides. Two of these are insulin-like growth factor I (IGF I) and insulin-like growth factor II (IGF II)3, so called because they are closely related to insulin in structure^{4,5}. IGF I and IGF II have somatomedin activity in vitro 6,7 but until now insufficient amounts of the peptides have been available to test their in vivo activity. We now report that pure IGF I stimulates the growth of hypophysectomized rats in a dose-dependent manner. This strongly supports the notion that the action of growth hormone is mediated by peptides of the somatomedin family.

The in vitro effects of insulin-like growth factors have been extensively studied. Both IGF I and IGF II are potent stimulators of cell replication, and of DNA and RNA synthesis in fibroblasts⁷, chondrocytes³ and calvarian cells (ref. 8 and C. Schmid and E.R.F., in preparation). Moreover, they mimic the effects of insulin on insulin target tissues such as adipose tissue⁷ and muscle⁹.

The recent development of specific antibodies against IGF I (ref. 6) and somatomedin C (ref. 10) have made it possible to investigate in man the dependence of these factors on the growth hormone (GH) status in various pathophysiological situations. Available evidence indicates that immunoreactive IGF I and somatomedin C are identical¹¹⁻¹³. The following clinical findings support the somatomedin concept²: immunoreactive IGF I is decreased in hypopituitarism and increased in acromegaly⁶. Treatment of hypopituitary children with growth hormone increases the serum immunoreactive IGF I levels¹⁴. Similarly, treatment of hypophysectomized rats with growth hormone causes a rise in their decreased serum IGF level¹⁵. Although clinical findings and in vitro results support the notion that IGF rather than growth hormone itself is the true growth stimulating hormone, there is no unequivocal direct evidence for this. There have been recent reports 16,17 that plasma peptide fractions containing somatomedin activity caused an increase in body weight and sulphate-incorporating activity of cartilage in Snell dwarf mice when administered subcutaneously three times per day for 2-4 weeks. Whereas van Buul-Offers et al. 16 also found an increase in nose-to-tail length, Holder et al. 17 observed no such effect. To prevent hypoglycaemia in the animals after bolus injections of the somatomedin preparation, van Buul-Offers et al.16 had to add 10% glucose to the drinking water. The latter problem was circumvented by Ellis et al. 18, who demonstrated that continuous subcutaneous (s.c.) infusion of a partially purified (4% purity) IGF preparation stimulated growth of hypophysectomized rats. The latter, in contrast to Snell dwarf mice, do not grow under thyroxine treatment, and therefore appear to represent a more specific experimental model for testing the somatomedin hypothesis. Therefore in this study we used hypophysectomized rats.

Male Tif RAI rats (100-120 g) were used for all experiments. Hypophysectomy was carried out 3-5 weeks before starting the experiments. Only those rats whose body weight did not increase by >0.2 g per day were considered to be totally hypophysectomized. The rats had free access to food (Altromin; Lage, FRG) and drinking water, and were kept on a 12-h light and dark cycle. Two doses of pure IGFI (43 and 103 µg per day)

Fig. 1 Stimulation of various growth indices by administration in vivo of IGF I and HGH to hypophysectomized rats (a = tibial epiphyseal width, thymidine incorporation into rib cartilage; c = daily body weight gain) Hormones were administered to groups of four rats for 6 days by continuous minipumps. IGF I was dissolved in 0 1 M acetic acid (43 or 103 μg per day); HGH (12.4 mU or 25 mU per day) (2 U mg⁻¹); Nordisk (Nanormon Insulin Laboratory, Denmark) was dissolved in saline. No difference was found between control rats treated for the same period with 0 1 M acetic acid or saline or left untreated. . Control hypophysectomized rats; II, IGF Itreated hypophysectomized rats; E, HGH-treated hypophysectomized rats. Each bar represents the mean \pm s.d. (n=4). *P<0.001; §P<0.01 compared with control (Student's *t*-test). $\dagger P < 0.01$, $\ddagger P < 0.05$ compared with the lower dose of hormone (Student's

were administered continuously for 6 days via s.c. implanted Alzet minipumps (no. 2001; Alza). The pumps (mean pumping rate $1.02\pm0.15\,\mu\text{l}\,\text{h}^{-1}$, mean filling volume $219.2\pm8.7\,\mu\text{l}$), were implanted under light ether anaesthesia. The pure IGF I preparation used was the same as that isolated and sequenced elsewhere4; its specific biological activity, as determined in the rat fat pad assay, was 330 mU mg⁻¹ (ref. 7). Pure IGF I was dissolved in 0.1 M acetic acid.

The body weight of the rats was measured daily at 08.00 h and they were killed after 6 days. The two lowest ribs were removed and ³H-thymidine (³H-TdR) incorporation into DNA was determined as follows: segments of cartilage were prepared free of perichondrial tissue and incubated (24 h, 37 °C) in Krebs-Ringer-phosphate buffer containing human serum albumin (2 mg ml⁻¹), nonessential amino acids (1% v/v; 5832 Difco), amino acids HeLA (1% v/v; 5790 Difco), glycine (0.2 mM), glutamine (2 mM) and ³H-TdR (1 μM). After incubation the cartilages were dried and weighed, digested in concentrated (90%) formic acid (30 min, 90 °C), then counted for radioactivity in 10 ml Instagel (Packard) in a β counter. The tibia test was carried out according to Greenspan et al. 19. The concentration of IGF I was determined by radioimmunoassay (RIA) before the minipumps were filled and after they were removed. The IGF I concentration was $1.88~\mu g~\mu l^{-1}$ in one group of rats before and $1.90~\mu g~\mu l^{-1}$ after 6 days of infusion. Thus, the IGF I concentration did not decrease in the implanted minipumps during 6 days under the skin.

Blood was sampled by aortic puncture and immunoreactive IGF I in pooled serum was determined by RIA. IGF I concentrations were 168 ng ml⁻¹ and 286 ng ml⁻¹, respectively, in the two IGF I-infused groups of rats. No immunoreactive IGF I was detectable in control and growth hormone-treated rats. The endogenous rat IGF, which increases after growth hormone treatment¹⁵, does not cross-react in the RIA with human IGF I. The lower dose of IGF I (43 μg per day) stimulated an increase in the tibial epiphyseal width (Fig. 1a) to 139%, the

higher dose (103 µg per day) to 168% compared with controls. The effect of IGF I was similar to that obtained in hypophysectomized rats treated with human growth hormone (HGH); whether administered by continuous s.c. infusion or by two intraperitoneal injections daily, HGH (12.5 or 25 mU per day) caused stimulation of growth to 157 and 176%, respectively,

Figure 1b shows DNA synthesis in vitro in costal cartilages of the same rats. IGF I (43 µg per day) increased ³H-TdR incorporation to 171%, and 103 µg per day to 239% compared with controls. Again the effect of HGH was similar: an increase to 172% (12.5 mU per day) and 265% (25 mU per day) was observed. The gain in body weight (Fig. 1c) during IGF I infusion was also comparable to that obtained during HGH administration.

Thus, IGF I administered to hypophysectomized rats mimics the effects of GH on these important indices of growth. Longitudinal growth is stimulated directly by IGF I. Our results strongly support the somatomedin concept2; however, they do not exclude other indirect and direct effects of GH on various tissues.

We thank Mr Meier and Dr Maier for supplying the hypophysectomized rats and Cristina Hauri and Therese Steiner for technical assistance. This work was supported by grant no. 3.380-0.78 from the Swiss NSF.

³H-noradrenaline release potentiated in a clonal nerve cell line by low-intensity pulsed magnetic fields

Richard Dixey

Department of Medical Electronics, St Bartholomew's Hospital, West Smithfield, London EC1A 7BE, UK

Glen Rein

Department of Chemical Pathology, Queen Charlotte's Maternity Hospital, London W6 0XG, UK

Recent studies have shown that extremely low-frequency (ELF) electric fields¹ and radiofrequency amplitude-modulated electromagnetic fields^{2,3,28} can influence ion fluxes in neural tissue. Furthermore, the application of low-frequency magnetic (LFM) fields in the successful treatment of non-union fractures and pseudo-arthrosis has been widely reported4-6. Stimulated by these findings and the wide variety of effects reported in other biological systems⁷⁻¹⁰, we have set out to establish a model system for studying the biological effects of such low-frequency fields that readily allows analysis of their mechanism of action. Clonal lines in tissue culture are an obvious choice for such a model, first, because the analysis is simplified by the presence of only one cell type and second, because the geometry of the biological sample can be specified to allow precise quantitation of applied field strengths and induced current densities. One such clonal line, designated PC12, is a likely candidate for such an approach as it expresses many properties of differentiated sympathetic neurones¹¹⁻¹⁶, including calcium-dependent release of neurotransmitters^{11,12,14}. We report here that ³H-noradrenaline(NA) release from PC12 cells is stimulated by an inductively coupled 500-Hz LFM field with a magnitude comparable with certain cholinergic stimuli in this system.

PC12 cells are derived from a transplantable rat phaeochromocytoma¹⁵; they synthesize, store and release dopamine, noradrenaline and acetylcholine¹¹⁻¹³ and express sodium action potentials¹⁶. In these experiments, PC12 cells were grown in Dulbecco's modified Eagle's medium containing 5 g l⁻¹ glucose, supplemented with 10% calf serum and 5% horse serum in the absence of nerve growth factor.

A magnetic field was generated by passing current through a pair of concentric 400-turn coils, 10.6 cm in diameter, separated by 14.7 cm. Two culture dishes were placed symmetrically between the coils at heights of 4.95 and 9.75 cm from the bottom coil. The changing magnetic field induces circulating eddy currents in the conducting medium in the dishes, with the current density increasing from zero at the centre to a maximum at a distance approximately equal to the coil radius. The range of currents so induced was limited by containing the cells in an annulus. This was achieved by gluing a small inverted Petri dish into the centre of the 60-mm sample dish and plating the cells in the annular channel so formed. This limits the range of induced current densities to within ±20% of the mean¹⁷. The magnetic field was generated between the coils by wiring them in parallel to a pulse generator and driving circuit similar to that used in clinical trials for the treatment of non-union fractures in Newcastle and London (P. O. Byrne and D. Outram, in preparation). The generator gives a train of square pulses with a range of different pulse durations, frequencies and intensities17

For these experiments we used a pulse width of 0.6 ms, with 1.4 ms between each pulse, giving an overall frequency of 500 Hz. The current waveform was smoothed due to the large inductance of the coils (Fig. 1). The applied magnetic field will have the same form as the current in the coils and can be calculated from the geometry of the coils and the current 17,18 . The maximum field applied to the sample was 8.5×10^{-4} WB m $^{-2}$ (8.5 G) and the minimum 1.6×10^{-4} Wb m $^{-2}$ (1.6 G). The rate of change of the magnetic field, calculated from the voltage induced in a search coil, varied between +1.8 and -0.9 Wb m $^{-2}$ s $^{-1}$, and the calculated circulating eddy current density varied between +0.025 and -0.013 A m $^{-2}$, inducing an electric field ranging from +3.8 $\times10^{-2}$ to -1.9×10^{-2} V m $^{-1}$.

³H-NA release was measured using logarithmic-phase PC12 cells by a modification of the procedure of Greene and Rein¹². After 2 h incubation with ³H-NA, cytoplasmic NA stores were

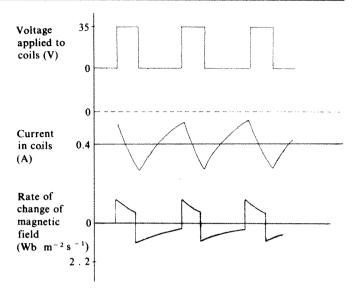

Fig. 1 Waveform generated by the low-frequency magnetic field generator. The magnetic field was calculated from the total measured current I in the coils using the formula

$$B_{z} = \mu \mu \frac{I}{2} \times \frac{na^{2}}{2} \left[\frac{1}{(z_{1}^{2} + a^{2})^{3/2}} + \frac{1}{(z_{2}^{2} + a^{2})^{3/2}} \right]$$

where a = radius of the coils, n = number of turns, and z_1 and z_2 are distances from each coil to point of calculation. $\partial B_z/\partial t$ was calculated from the voltage (V) induced in a search coil of area A and N turns: $V = NA \partial B/\partial t$ (refs 17, 18).

largely depleted as the NA was spontaneously released from the cells during a 3.5-h washout period. Release was then monitored for 12 sequential 15-min periods. At the 105- and 120-min time periods (designated experimental), two dishes were removed from the Numetal shield, which protects the cells from stray magnetic fields, and placed between the coils for a total of 13 min. To eliminate the possibility that LFM fields dislodge cells into the medium, thereby generating artificially high values, medium from the cells was centrifuged at 2,200g for 5 min before assaying for radioactivity. The pellets were solubilized and counted separately.

In all 10 trials in which the LFM fields were applied, release values (c.p.m.) obtained at 105 and 120 min were always higher than the values obtained from the two preceding time periods. To estimate the extent of the observed stimulation, the first six release values for all 22 trials were fitted to the polynomial function $\log Y = \phi(x) + N + T$ from which the control curve of Fig. 2 is obtained; Y represents the c.p.m. in the supernatants, x is the time in minutes, N is a normalizing term allowing direct comparison between dishes and T is a term inserted for the experimental period¹⁹. In the control dishes (n = 12) the observed values for the experimental periods fitted within 1 s.d. of those obtained by extrapolating the polynomial function,

Table 1 ³ H-noradrenaline release from PC12 cells							
c.p.m. expressed as %	Time (min)						
of cell content	n	90	105	120	135		
Control	12	0.717 ± 0.039	0.686 ± 0.046	0.657 ± 0.044	0.628 ± 0.033		
Experimental	10	0.717 ± 0.039	0.875 ± 0.064	0.838 ± 0.061	0.628 ± 0.033		
Experimental + 15 mM Mg ²⁺	8	0.717 ± 0.039	0.673 ± 0.015	0.686 ± 0.02	0.628 ± 0.033		
Pellets	10	0.049 ± 0.012	0.05 ± 0.014	0.045 ± 0.013	0.06 ± 0.024		

Release values were generated by regression analysis and expressed graphically as in Fig. 2. In the elevated Mg²⁺ trials the medium for the 105- and 120-min time periods, during field stimulation, contained 15 mM MgSO₄. The aspirated medium was treated as described in Fig. 2 legend. Pellets obtained from spinning aspirated medium (experimental series) at 2,200g for 5 min were solubilized in 1.5 ml of 1 M NaOH and assayed for radioactivity in 10 ml Instagel. All values are expressed as a percentage of the residual intracellular radioactivity and are shown as mean ± s.e.m.

showing that the washout curve varies smoothly with time. The experimental values (during LFM field stimulation) were elevated above the controls, with the treatment effect being highly significant (P < 0.001).

Expressing the stimulated release as the difference between the control and experimental values relative to the control value for a given time period, a percentage stimulation (±s.e.m.) of $27.5\% \pm 4.9$ is obtained for both experimental time periods. This elevation is likely to be due to increased release of NA from the cells in monolayer and not to contamination by LFM field-induced floating cells, because the pellet counts for the experimental periods are not significantly different (P > 0.5)from those before or after it (see Table 1). The temperature of the coils was continuously monitored and did not rise above the 37 °C of the CO₂ incubator.

In eight further trials in which 15 mM Mg²⁺ was included in the medium for the experimental periods, the rate of release in control washout curves did not alter, but the stimulated release was abolished (see Table 1). The stimulated release

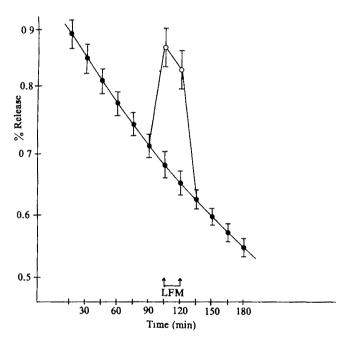

Fig. 2 Effect of a 500-Hz pulsed magnetic field on noradrenaline release from PC12 cells. This curve was generated by regression analysis from a population of 22 curves. Cells were grown in collagen-coated annular dishes made by gluing an inverted 35-mm dish to a 60-mm dish. All manipulations were carried out in a 37 °C warm room. Logarithmic cells (~1×10⁶ cells per dish) were incubated for 2 h in Dulbecco's modified Eagle's medium containing 1 mM (-)sodium; ascorbate and 2 μCi ³H-(-) NA(11 Ci/mmot⁻¹; Amersham) in a CO₂ (7%) incubator maintained at 37 °C. The radioactive medium was then removed and the cells washed three times with fresh medium (at 37 °C). The cells were incubated in a 37 °C/CO₂ atmosphere for an additional 3.5 h in 1.5 ml fresh medium. During this time, the medium was changed after 2 h and then at 30-min intervals. Thereafter the medium (1.5 ml) was changed every 15 min for 12 consecutive periods. The medium from these changes was transferred to polypropylene tubes and centrifuged at 2,200g for 5 min to pellet gently any floating cells. The supernatants were then assayed for radioactivity in 10 ml Instagel (Packard). At the end of each experiment, radioactivity remaining in the cells was assayed by scraping the cells sequentially in 0.5 ml 1 M HCl, 0.5 ml 1 M NaOH and 0.5 ml water. The pooled scrapings were then assayed for radioactivity as above. Release values were calculated from the ratio of the c.p.m. in the supernatant, at a given time period, to the total residual intracellular radioactivity at the end of the experiment. The mean total intracellular count (±s.e.m.) was $389,018\pm26,827$. We have shown previously that 84% of the radioactivity released from the cells is unmetabolized NA¹². \bullet , Control curve, O, Stimulated points.

values in the presence of elevated Mg^{2+} were not significantly different from the controls (P>0.3). In three of the trials, following exposure to 51.5 mM K⁺ (ref. 11) following the period of stimulation by the LFM, the cells released a substantial proportion of their NA store, indicating that irreversible damage had not occurred.

These results suggest that PC12 cells can be used as a model system for studying the effects of LFM fields on neuronal functions. Release of catecholamines (spontaneous or preloaded with ³H-NA) from PC12 cells can be induced by depolarizing concentrations of K⁺ (refs 11, 14), the sodium ionophore veratridine 11, or by activating acetylcholine receptors with nicotine¹² or carbamylcholine¹⁴. Whereas the maximum stimulation of NA release induced by nicotine $(10 \,\mu\text{M})^{12}$ is ~300% in similar experimental conditions to those used here, the acetylcholine analogue carbamylcholine (100 µM) induced a 60% stimulation of release (L. A. Greene and G.R., unpublished observation). The 27.5% stimulation observed here may not be maximal, as a dose-response curve has not yet been established, but is still of comparable magnitude with that obtained with certain cholinergic stimuli.

Previous studies on Ca2+ efflux from chick and cat cerebrum have stressed the importance of a 6-20-Hz frequency 'win $dow^{20,21}$, although an initial report on efflux of γ -aminobutyric acid in the cat cortex showed a small increase induced by a 200-Hz directly coupled signal²². In the experiments reported here release was induced by a 500-Hz pulsatile waveform. Clearly the frequency dependence needs further investigation and studies are under way to determine the effect of different stimulation frequencies and the importance of the pulse shape and modulation.

The observation that Mg2+ inhibits the LFM field-induced release from PC12 cells indicates a requirement for extracellular Ca²⁺, as Mg²⁺ has been shown to be a specific Ca²⁺ antagonist in several biological systems²³. Because depolarization-induced release is also inhibited by Mg²⁺ in PC12 cells^{11,12,14}, it is possible that LFM field-induced release occurs via a similar exocytotic mechanism in which Ca2+ fluxes are involved24. However, on biophysical grounds alone, the direct imposition of Ca2+ entry by this LFM field is an unlikely hypothesis, because we estimate that the maximum electric field intensity is $\sim 4 \times 10^{-2} \text{ V m}^{-1}$, far less than the 10^3 V m^{-1} field associated with a typical action potential. A more plausible hypothesis is that the cation binding sites on the outer surface of the plasma membrane may be highly sensitive to such weak stimuli²⁰ and that subsequent cooperative changes in Ca2+ binding may influence membrane stability, thereby promoting Ca²⁺ entry and vesicular release.

Clearly, this physical stimulus offers a new approach for studying the mechanisms involved in stimulus-secretion coupling²⁴ as well as having important and widespread clinical implications.

We thank Dr Michael Lunt for the design and characterization of the physical approach, Mr Nigel Hathway for assistance in analysing the results and the Smith's Charity for supporting R.D. during this study.

Agonist selectivity and second messenger concentration in Ca²⁺-mediated secretion

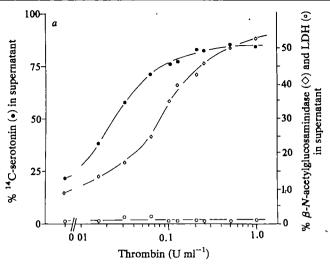

D. E. Knight*, T. J. Hallam & M. C. Scrutton

Departments of Physiology* and Biochemistry, King's College, Strand, London WC2R 2LS, UK

Cells typically carry receptors for several excitatory and/or inhibitory agonists. In many cases the pattern of response observed is characteristic of the particular agonist used 1-4. These differences in the nature of the responses cannot always be explained on the basis that the agonists use different intracellular second messengers³⁻⁵. For example, in the blood platelet, Ca2+ seems to be the second messenger6 for such excitatory agonists as ADP, adrenaline, thrombin, collagen and 11-epoxymethanoprostaglandin H₂ (U-46619). These agonists cause secretion of serotonin, ADP and ATP from the amine storage granules whereas secretion of acid hydrolases from the lysosomes has been reported to occur only on stimulation by higher concentrations of collagen and thrombin⁷⁻¹¹. We have investigated this agonist selectivity and report here results suggesting that it is not related to cytosolic Ca²⁺ concentration.

Figure 1a illustrates the dose-response curves observed for release of serotonin, β -N-acetylglucosaminidase and lactate dehydrogenase when washed human platelets are challenged with thrombin. The concentration (EC₅₀) of thrombin required for half-maximal release of serotonin (0.02 U ml⁻¹) is significantly lower than that of β -N-acetylglucosaminidase (0.09 U ml⁻¹), while no significant release of the cytosolic marker enzyme, lactate dehydrogenase, is observed over the range of thrombin concentration tested. In accord with these observations, data from experiments performed in different conditions reveal a nonlinear relationship between the thrombin-induced release of serotonin and β-N-acetylglucosaminidase from intact platelets, with serotonin being preferentially released at low thrombin concentration (Fig. 1b). This selectivity in the response to thrombin could be explained if secretion of acid hydrolases occurs only when the cytosolic Ca²⁺ concentration is higher than is required for secretion from the amine storage granules. We have therefore examined secretion of serotonin, ADP and β -N-acetylglucosaminidase by washed platelets rendered permeable by exposure to an intense electric field, thereby allowing their internal calcium concentration to be varied1

shows the release of serotonin, β -Nacetylglucosaminidase and lactate dehydrogenase measured as a function of Ca²⁺ concentration for platelets rendered permeable and then challenged with Ca2+ buffers. Release of β -N-acetylglucosaminidase is observed over the same range of Ca2+ concentrations as release of serotonin, but in accord with earlier observations¹² there is no significant Ca²⁺-dependent release of lactate dehydrogenase. The pattern of serotonin and B-N-acetylglucosaminidase release observed in the permeable cells (Fig. 2) contrasts markedly with that observed when the intact cells are challenged with thrombin (Fig. 1a). From the log₁₀ dose-response relationship observed in several experiments using the permeable cells, the EC₅₀ for Ca²⁺-induced release of β -N-acetylglucosaminidase is calculated to be 1.8 \pm

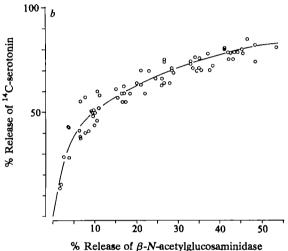

Fig. 1 a, The relationship between the extents of release of -C-serotonin (\bullet), β -N-acetylglucosaminidase (\diamond) and lactate dehydrogenase (LDH, O) and thrombin concentration for intact human platelets. Human blood platelets were suspended in 0.28 M sucrose containing 0.02 M PIPES, 0.01 M K+-glutamate, 2 mM MgCl₂ and 0.4 mM EGTA pH 6.6 as described previously Aliquots (0.25 ml) were challenged with various concentrations of thrombin for 5 min at 20 °C before being centrifuged for 2 min at 8,000g. The supernatant fraction was removed and aliquots taken for assay of ¹⁴C content (50 µl), lactate dehydrogenase (100 μ l) and β -N-acetylglucosaminidase (50 μ l). Lactate dehydrogenase was assayed spectrophotometrically and β -N-acetylglucosaminidase fluorimetrically The C, lactate dehydrogenase was assayed spectrophotometrically and β -N-acetylglucosaminidase fluorimetrically S. The C, lactate dehydrogenase was assayed spectrophotometrically and β -N-acetylglucosaminidase fluorimetrically S. The C, lactate dehydrogenase was assayed spectrophotometrically S. The C, lactate dehydrogenase was assayed spectrophotometrically S. The C, lactate dehydrogenase was assayed spectrophotometrically S. The S. The S. The C. Lactate dehydrogenase was assayed spectrophotometrically S. The S. drogenase and β-N-acetylglucosaminidase contents of the supernatant fractions are expressed as per cent of the total content of the platelet suspension. The total contents of lactate dehydrogenase and B-N-acetylglucosaminidase in the platelet suspension were typically 120 mU ml⁻¹ and 10.0 mU ml⁻¹ respectively. Essentially similar results were obtained when the platelets were suspended in media at pH 7.4 and over a range of Ca-EGTA buffers (10 mM) corresponding to $\sim 10^{-8}-10^{-5}$ M Ca²⁺. b, The relative amounts of β -N-acetylglucosaminidase compared with ¹⁴C-serotonin released from intact platelets incubated in various concentrations of thrombin and in conditions as in a. The amounts released are expressed as a per cent of their cellular content.

 $0.1 \,\mu\text{M}$ (n = 7), in good agreement with the value of $1.9 \pm$ 0.9 µM determined previously for serotonin release 12. The EC₅₀ is independent of the concentration of EGTA in the Ca²⁺ buffer over the range 5-50 mM, suggesting that this release results from the direct action of micromolar concentrations of Ca2+ on the secretory apparatus, rather than through Ca²⁺-induced release of Ca^{2+} from intracellular stores. The release of β -Nacetylglucosaminidase in this system is smaller than that observed for serotonin, a finding which agrees with the relative

release of B-N-acetylglucosaminidase and serotonin observed both here (Fig. 1) and in previous studies^{7,9} on stimulation of intact platelets by high concentrations of thrombin.

Release of β -N-acetyglucosaminidase is complete within seconds of challenging permeable cells with $10^{-5}\,\mathrm{M\,Ca^{2+}}$, and in a variety of conditions is closely correlated (Fig. 3) with release of both serotonin and ADP, the major nucleotide present in the amine storage granules of human platelets¹³. In contrast, no correlation is observed in these conditions between the release of these constituents and that of lactate dehydrogenase (Fig. 3). In the case of ATP an intermediate situation is observed, as might be expected because significant concentrations of this nucleotide are present in both the cytosol and the amine storage granules of human platelets¹³.

Our data therefore provide further evidence that exocytosis can be induced in human platelets as an immediate consequence of an increase in cytosolic Ca2+ concentration and demonstrate

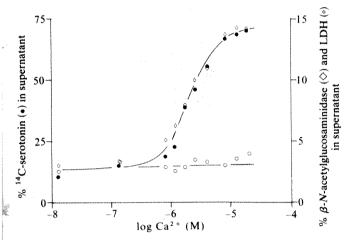

Fig. 2 The relationship between the extents of release of ¹⁴Cserotonin (•), β-N-acetylglucosaminidase (◊) and lactate dehydrogenase (O) and the Ca2+ concentration in human platelets rendered permeable by exposure to a 20-kV electric field. Human blood platelets were obtained and suspended in 0.28 M sucrose containing 0.2 M PIPES, 0.01 M K+-glutamate, 5 mM ATP, 7 mM MgCl₂ and 0.1 mM acetylsalicylic acid pH 6.6 as described previously ¹². After addition of 0.4 mM EGTA the suspension was exposed to an electric field of 20,000 V cm⁻¹ with a time constant of 30 μ s as described previously ¹² and aliquots (0.25 ml) were then immediately challenged with 10 mM Ca-EGTA buffers. The free ionized calcium concentrations were calculated using equilibrium constants of $10^{-5.928}\,\mathrm{M}$ (Ca-EGTA), $10^{-1.445}\,\mathrm{M}$ (Mg-EGTA), $10^{-3.538}\,\mathrm{M}$ (Ca-ATP) and $10^{-3.675}\,\mathrm{M}$ (Mg-ATP)¹⁶. After incubation for 5 min at 22 °C the samples were centrifuged for 2 min at 8,000g and the supernatant fractions removed. Aliquots were assayed for 14 C-serotonin, lactate dehydrogenase and β -Nacetylglucosaminidase as described in Fig. 1. The contents are expressed as a per cent of the total contents of the platelet suspension. Before exposure to the electric field, 5% of the 14 and 2% of the lactate dehydrogenase and the β -N-acetylglucosaminidase were present in the extracellular medium. Control studies have shown that: (1) the properties of release of 14 C-serotonin and β -N-acetylglucosaminidase do not differ significantly if acetylsalicylic acid is omitted from the suspending buffer; (2) leakage of ATP, which occurs in the presence of 10⁻⁹ M ⁺, is complete at the earliest time (30 s) that could be examined after exposure to the electric field; and (3) no significant leakage C-serotonin, lactate dehydrogenase, B-N-acetylglucosaminidase or enolase resulted from exposure to the electric field in the presence of $10^{-9}\,\mathrm{M\,Ca}^{2+}$. These latter observations establish that the membranes of the amine storage granules and the lysosomes are not damaged by exposure to the electric field and that the 'pores' created in the plasma membrane are large enough to allow free passage of molecules of molecular weight <500 but too small to permit leakage of proteins of molecular weight >80,000. Further studies are required to define the behaviour in this system of cellular constituents having molecular weights between these two values.

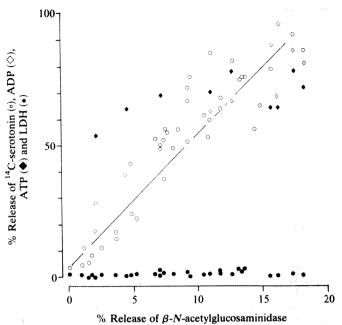

Fig. 3 The relative amounts of β -N-acetylglucosaminidase with -serotonin (○), ADP (♦), ATP (♦) and lactate dehydrogenase () released from human platelets incubated in various conditions after exposure to an electric field as described for Fig. 2. Human platelets were prepared, washed and rendered permeable as described for Fig. 2 except that where ADP and ATP were measured, the medium contained 2 mM MgCl₂ and ATP was omitted. ATP and ADP were assayed as described previously The amounts of all components assayed are expressed as per cent of total cellular content. The total contents of ATP and ADP in the platelet suspension were 3.3 and 2.2 μ M respectively. After exposure to the electric field in the presence of 10^{-9} M Ca²⁺ the ATP and ADP contents of the supernatant fraction were 2.5 and $0.4 \mu M$ respectively. The correlation coefficients between β -N-acetylglucosaminidase and 14 C-serotonin, ADP, ATP and lactate dehydrogenase are 0.92 (n=40), 0.95 (n=9), 0.60 (n=9) and 0.37 (n = 33) respectively. The line shown is a linear regression of 14 C-serotonin release on β -N-acetylglucosaminidase release and has a slope of 5.0 ± 0.4 ($\pm s.d.$).

that the increase in Ca2+ concentration required is not significantly different for platelet amine storage granule and lysosomal secretion. Hence, the agonist selectivity observed for secretion of the constituents of these two granules is likely to result from an event in the stimulus-response coupling mechanism other than that responsible for altering the concentration of Ca² in the platelet cytosol.

Monoclonal antibody against human IFN-γ

H. K. Hochkeppel

Gesellschaft für Biotechnologische Forschung mbH, Mascheroder Weg 1, D-3300 Braunschweig, FRG

M. de Ley

Rega Instituut, Minderbroedersstraat 10, B-3000 Leuven, Belgium

Monoclonal antibodies have proved extremely useful for the unambiguous identification, quantification and large-scale purification of a given antigen or a specific epitope. As they are highly specific for a given antigenic determinant, these antibodies are superior to conventional polyclonal antibodies. Since the discovery1 that mouse spleen B lymphocytes can be fused with mouse B-myeloma cells to yield hybrid cells (hybridomas) secreting specific antibodies derived from the spleen cell fusion partner, several modifications of this method have been used to improve the yield of surviving antibodysecreting hybridomas. We have now included, 5 days after the fusion proceedure, an additional step which stabilizes the hybrids against gene loss and improves growth conditions. We report here that, using this method, we have established several stable mouse hybridoma lines secreting monoclonal antibodies to human γ-interferon (HuIFN-γ).

HuIFN- γ was obtained from buffy coats after induction with concanavalin A and subsequently purified by controlled-pore glass adsorption and Sephacryl S200 column chromatography². BALB/c mice were immunized intraperitoneally (i.p.) every third week with 20 units of the HuIFN- γ in a mixture of incomplete Freund's adjuvant and N-acetylmuramyl-L-alanyl D-isoglutamine. Three days before fusion the mice were given a final booster (seventh immunization) subcutaneously of 60,000 units of HuIFN- γ in incomplete Freund's adjuvant. The fusion of mouse spleen lymphocytes and mouse (FO) myeloma cells was performed as described by Hochkeppel *et al.*³. After fusion, the hybridomas were first cultured for 5 days in hypoxanthine-aminopterin-thymidine (HAT) medium containing

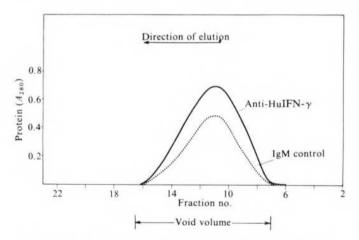

Fig. 1 Elution profile of monoclonal anti-HuIFN- γ on Sephadex G-200. Hybridoma supernatants (10 ml) containing \sim 1–5 μg ml $^{-1}$ of antibody were precipitated with 40% ammonium sulphate (ice-cold) and the precipitated proteins, after resuspension in 200 μl Tris-buffered saline pH 7.4, were further purified by filtration on a 10 ml Sephadex G-200 filtration column in Tris-buffered saline, pH 7.4. At this protein concentration no IgG protein peak was visible. The antibody eluted with the void volume and had an elution profile identical to that of an IgM control.

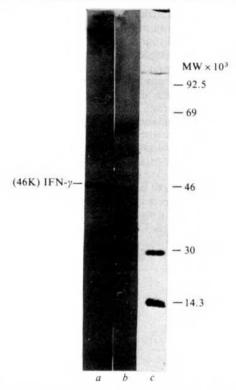

Fig. 2 ELISA using HuIFN-y and monoclonal anti-HuIFN-y. Partially purified HuIFN-y which had been pretreated with 0.1 M SDS alone was separated, in parallel with ¹⁴C-labelled standard proteins, by SDS-polyacrylamide gel electrophoresis according to Laemmli⁵. All proteins were electrophoretically transferred to a nitrocellulose sheet according to Towbin *et al.*⁶. While the section of the blot containing marker proteins was subjected to autoradiography, ELISA was performed on the section containing HuIFN-γ. First the blot was saturated for 2 h with 3% bovine serum albumin (BSA)/5% horse serum to block all the nonspecific binding sites. After washing with Tris-buffered saline, monoclonal anti-HuIFN-γ (10 μg ml-1) purified from hybridoma culture supernatants was added at a dilution of 1:50 and incubated at 25 °C for 16 h. Subsequently rabbit IgG directed against mouse IgM was added at a 1:200 dilution in 5% horse serum, 0.5% BSA (4 h, 25 °C) and finally goat peroxidase-conjugated IgG directed against rabbit IgG (1:500; 2 h at 25 °C). The reaction was followed by observing the colour change with O-dianisidine used as a substrate for H2O2. a, HuIFN-y plus monoclonal anti-HuIFN-γ; b, HuIFN-γ plus medium (control); c, 14C-labelled standard proteins.

Iscove's modified Dulbecco's medium (IMDM) supplemented with 20% fetal calf serum (FCS) and 1% methylcellulose. After 1 week, with 20% of hybridomas surviving, half of each individual culture was injected into the peritoneal cavity of separate BALB/c mice which had been pretreated with pristane for 1 week⁴. (The other half was cultured further in HAT medium.) One week after injection, ascites fluids were collected and the hybrids cultured in IMDM +10% FCS. Of 16 stable lines secreting monoclonal anti-HuIFN- γ , 15 were isolated from those cultures which had been passaged through a mouse after fusion.

These hybridomas were subcloned in Greiner 'single clone' 24-well tissue culture plates in which each of the wells was divided into 16 subsquares. As the FO hybridomas grow attached to the well surface, these subdivided wells are a convenient tool for subcloning. Growing colonies were tested for specific anti-HuIFN- γ secretion in an antiviral neutralization test on human CCL 23 cells. Briefly, the surface of microtitre immunoassay plates were coated with rabbit anti-mouse immunoglobulin, and the supernatants of individual mouse hybridoma cultures were incubated in these plates for 16 h. After a final wash, 10 units of HuIFN- γ were added to each

individual well and the plates were incubated at 37 °C for 4 h. The remaining antiviral activity in each cup was then titrated in a viral RNA reduction assay using vesicular stomatitis virus on human CCL 23 cells. By thus testing the individual anti-IFN-γ hybridoma lines for constant antibody secretion over a period of 6 months, 16 stable mouse hybridoma lines secreting monoclonal anti-HuIFN-y were established. So far, we have characterized the monoclonal antibody of one of these lines.

To identify the immunoglobulin species of this monoclonal anti-HuIFN-y, the antibody was purified from hybridoma supernatants by ammonium sulphate (40%) precipitation followed by gel filtration on Sephadex G-200. The anti-HuIFN-γ eluted in the void volume with an elution profile identical to that of an IgM control (Fig. 1). The specificity of the purified monoclonal anti-HuIFN-y was tested further in an enzyme-linked immunosorbent assay (ELISA) against HuIFNy which had been separated by SDS-polyacrylamide gel electrophoresis⁵ (omitting β -mercaptoethanol treatment of the HuIFN-y sample) and electrophoretically transferred to a nitrocellulose sheet according to Towbin et al.6. Figure 2 shows

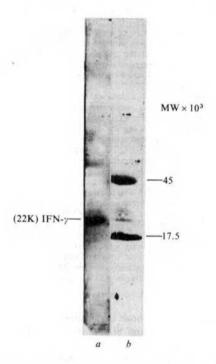

Fig. 3 ELISA using HuIFN-y and monoclonal anti-HuIFN-y. Partially purified HuIFN-y which had been pretreated with SDS and β -mercaptoethanol was separated in parallel with standard proteins by SDS-polyacrylamide gel electrophoresis according to Laemmli⁵. After electrophoretic transfer of all proteins to a nitrocellulose sheet, the section containing the standard proteins was stained with amido black. An ELISA was performed on the section containing the HuIFN-y as described in Fig. 2 legend. a, HuIFN-y plus monoclonal anti-HuIFN-y; b, standard proteins stained with amido black.

that the monoclonal anti-HuIFN-y specifically reacted with the HuIFN-y preparation at a position corresponding to molecular weight (MW) 46,000 (46K). The same experiment was carried out after treatment of the IFN-y preparation before SDSpolyacrylamide gel electrophoresis with SDS and β -mercaptoethanol to avoid possible dimerization of the HuIFN-y molecule. In these conditions the HuIFN-y blotted on to nitrocellulose reacted with monclonal anti-HuIFN-y at a position corresponding to MW 22,000 (Fig. 3). These results suggest that monoclonal anti-HuIFN-y is specifically directed either against two different HuIFN-y subspecies or against the dimer in one case (Fig. 2) and against the monomer in another (Fig. 3). However, the shifting of the immuno-reacting HuIFN-y

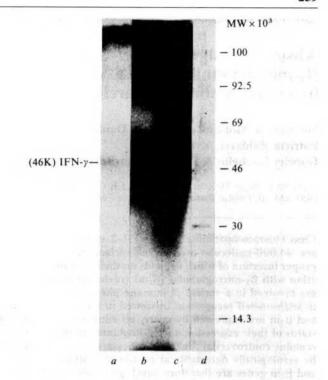

Fig. 4 Autoradiograph of a 15% SDS-polyacrylamide gel⁵ containing: *a*, immuno-purified ¹²⁵I-HuIFN-γ; *b*, wash fraction; *c*, original ¹²⁵I-HuIFN-γ; and *d*, ¹⁴C-labelled protein markers. Partially purified 125 I-IFN-y which had been incubated first with monoclonal mouse anti-HuIFN-y for 16 h and then with rabbit IgG antibody directed against mouse IgM (16 h) was precipitated with S. aureus protein A. The precipitate was washed four times with Tris-buffered saline, then the specifically bound ¹²⁵I-IFN-γ (pretreated with SDS, but not β -mercaptoethanol) was separated on an SDS-polyacrylamide gel⁵ in parallel with 14 C-protein markers, the wash fraction and the original 125 I-HuIFN- γ sample.

band after β -mercaptoethanol treatment makes the latter possibility more likely.

In a further experiment, partially purified HuIFN-y which had been labelled with 125I according to Hunter et al.7 was incubated first with monoclonal mouse anti-HuIFN-y and subsequently with a rabbit (IgG) anti-mouse IgM antibody. This complex was then precipitated with IgG-specific Staphylococcus aureus protein A. After several washes of the precipitate, the specifically bound ¹²⁵I-labelled IFN-γ was separated on an SDS-polyacrylamide gel according to Laemmli⁵ (without \(\beta\)mercaptoethanol treatment) in parallel with 14C-labelled protein markers. Autoradiography of the dried gel (Fig. 4) showed that monoclonal anti-HuIFN-y bound to S. aureus protein A, specifically precipitated ¹²⁵I-IFN-γ at 46,000 MW. Finally in an ELISA there was no cross-reaction of anti-HuIFN-y with either HuIFN-β or HuIFN-α which had been electrophoretically transferred from an SDS-polyacrylamide gel on to a nitrocellulose sheet, nor did monoclonal anti-HuIFN-β crossreact with HuIFN-y (data not shown).

HuIFN-β was a gift from Rentschler/Laupheim Co. and HuIFN-α was given by H. Mohr. M.L. is Bevoegdverklaard Navorser of the Belgian National Fonds voor Wetenschappelyk Onderzoek.

Absence of significant H-2 and β_2 -microglobulin mRNA expression by mouse embryonal carcinoma cells

Dominique Morello*, Françoise Daniel, Patricia Baldacci, Yvon Cayre, Gabriel Gachelin & Philippe Kourilsky

Unité de Biologie Moléculaire du Gène, ER CNRS 201, SC INSERM 20, Institut Pasteur, 75724 Paris Cédex 15, France

Class I histocompatibility antigens (H-2 antigens in the mouse) are 44,000-molecular weight cell-surface glycoproteins, the proper insertion of which depends on their noncovalent association with β_2 -microglobulin (β_2 m) (reviewed in ref. 1). They are involved in a variety of immune phenomena, particularly in self/non-self recognition (reviewed in ref. 2). H-2 antigens and B2m are expressed by nearly all adult somatic cells. The status of their expression on pre-implantation mouse embryos remains controversial^{3,4} although they are generally agreed to be serologically detectable at post-implantation stages⁵. H-2 and B₂m genes are therefore developmentally regulated. H-2 antigens have not been found on murine embryonal carcinoma (EC) cells⁶, which are widely used as an alternative to studying normal early embryonic cells⁷⁻⁹, but they become detectable during in vitro differentiation of EC cells¹⁰⁻¹². During studies aimed at understanding the genetic mechanisms involved in the expression of H-2 antigens and β_2 m during differentiation, cDNAs reverse transcribed from mRNAs coding for H-2 or H-2-related heavy chains and β2m have been characterized¹³⁻¹⁶. H-2 and β₂m cDNAs were used as probes to screen total poly(A)+ RNAs from various cell types. We report here that trace amounts of poly(A)+ RNA from EC cells were found to hybridize with these probes, finding which contrasts with results obtained on poly(A)+ RNA prepared from differentiated cells. These results, taken together with the absence of major rearrangements in H-2 and β2m genes during differentiation, suggest that H-2 and β₂m expression is likely to be controlled at the level of transcription.

Figure 1 legend describes the probes used in the study. Poly(A)+ RNAs were extracted from liver, spleen and kidney of DBA/2 (H-2^d) and 129/Sv (H-2^{bc}) mice. (These animals are respectively syngeneic to SL2 tumour cells, from which the to most of the EC lines used in the present study¹⁷). The poly(A)⁺ RNAs were electrophoraged in account study¹⁷). red to nitrocellulose sheets and finally hybridized with ³²P-labelled probes ¹⁸. Probes H-2A, B and C revealed the same unique band, corresponding to RNAs of ~1,800 nucleotides (Fig. 2, lanes b, c, results shown for H-2B probe), a size in good agreement with that estimated (17S) from sedimentation through sucrose gradient¹⁹. In the various H-2 cDNA clones studied so far^{20,21}, the 3'-untranslated region is ~480 nucleotides long, excluding the poly(A) tail. The coding region, estimated from the known amino acid sequence of H-2K^b (ref. 22), must be about 1,000 nucleotides long; assuming the poly(A) tail does not exceed 100 nucleotides, the length of the 5'untranslated region in H-2 mRNAs should be 100-300 nucleotides. We have detected no size difference nor any heterogeneity in the two mouse strains or in the various tissues tested (Fig. 2, lanes b,c and data not shown). The absence of heterogeneity implies that members of the H-2 multigene family, when expressed, yield mRNAs of an approximately similar size (in this size range, we could only detect a difference >100 nucleotides). Finally, if non-H-2 mRNAs are expressed and carry the reiterated sequence detected by probe C, they must fall within the same size ranges as H-2 mRNAs. Hybridization with the

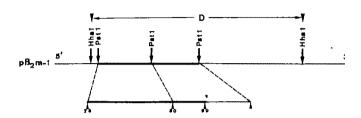

Fig. 1 Top. The restriction maps of the cDNA inserts of the recombinant plasmids $pH-2^d-3$ and $pH-2^d-1$ (refs 20, 24) are presented in correspondence with the linear structure of an H-2 antigen molecule M indicates the membrane spanning region with the external part of the molecule on the NH2-terminal side and the cytoplasmic fragment on the COOHterminal side. A, B and C represent restriction fragments used as radiolabelled probes in experiments described in the text. Probe H-2A is the 578-base pair (bp) Psh-Psh of pH-2^d-3²⁰ From its 5' end, it extends over the From its 5' end, it extends over the COOH-terminal part of an H-2 molecule (nucleotides 180-498, PvuII site), corresponding to part of the third external domain, transmembrane and cytoplasmic regions; the probe extends downstream over the first 260 bp of the noncoding region. This fragment does not contain a region hybridizing with a sequence highly repeated in the genome²⁴. Probe H-2B is the 938-bp Hha-Hha fragment of pH-2⁴-1¹³. The 5' part (up to the PvuII site) encodes for a nearly complete third extracellular domain, transmembrane and cyto-The 327-bp noncoding region downstream contains at its 3' end a stretch of 20 nucleotides belonging to the Alu type II sequence Probe H-2C is the 160-bp PstI-PstI fragment of pH-2d-3. Its 3' end includes the Alu type II sequence. This sequence is repeated a minimum of 40,000 times in the haploid genome of the mouse^{14,24}. Bottom The restriction map of the cDNA insert of the recombinant plasmid $p\beta_2$ m-1 is presented in correspondence with the linear structure of the β_2 m molecule. This clone has been obtained by screening a mouse cDNA library with a recently cloned human β_2 m cDNA probe¹⁶. p β 2m-1 includes most of the sequence coding for β_2 m and about 100 additional basepairs of the 3'-untranslated region. The restriction fragment D was used as the β_2 m probe.

 β_2 m probe reveals two bands of similar intensities, migrating approximately as 1,000 and 800 nucleotides in both DBA/2 (Fig. 2, lane d, and Fig. 3A, lanes e, f) and 129/Sv (Fig. 3A lane g) poly(A)⁺ RNAs. These two bands could correspond to either the same coding sequence associated with different untranslated regions or to products of two different genes.

Poly(A)+ RNAs were extracted from several EC lines, F9 PCC3 and PCC4-aza¹² and analysed as above. Using probes prepared at the usual specific radioactivity (2-3×108 c.p.m. pe μg), no poly(A)+ RNA was found to hybridize with the H-2B C and the β_2 m probes (Fig. 3A, lanes b-d; results shown with probes B and D) even with autoradiographic exposure for 2 weeks (data not shown). These poly(A)⁺ RNAs were considered as undegraded because they hybridized strongly with an actine probe, yielding an intense band with an apparent size of 2,000-2,100 nucleotides and no smear (Fig. 3B). When H-2 and β_2 m probes, displaying a much higher specific radioactivity (2× 10° c.p.m. per μg) were used, faint bands were observed or poly(A)+ RNAs extracted from EC cells, at the same location as in adult cells. No additional bands were observed on the latter control (Fig. 3C, lanes a, c). By comparison of the intensities of the bands obtained with similar amounts of poly(A)+ RNA prepared from EC and adult cells, we conclude that the former contained about 100 times less H-2- and β_2 m-specific mRNA than the latter. This result can be accounted for by either a normal expression in about 1% of the cells or by a 1% expression in most of them. Serological data¹¹ favour the first hypothesis.

Hybridization to H-2 and β₂m probes was carried out using poly(A)+ extracted from differentiated cells derived from EC lines by in vitro differentiation. We observed the same pattern as with poly(A)+ extracted from adult organs: one band migrating as ~1,800 nucleotides hybridizing with H-2 probe and two bands migrating approximately as 1,000 and 800 nucleotides hybridizing with β_2 m probe. The intensity of the bands was dependent on the relative amount of H-2 antigens expressed by the cells tested: faint bands are observed with mRNAs prepared from 3/A/1-D-3 (ref. 17), a fibroblastic line derived from PCC3 exhibiting a low amount of H-2 antigens (data not shown). The intensity of the bands observed with mRNAs prepared from C17-S1-D-T 984 (ref. 23), a muscle cell line isolated from a contractile zone of cultured cells derived from a C3H teratocarcinoma, indicates that there is about the same amount of specific H-2 and β_2 m mRNA in these cells as in adult cells (Fig. 3C, lanes b, c), confirming the immunofluorescence data.

These results suggest that there is about 1% of H–2 and β_2 m poly(A)⁺ RNA in EC cells as compared with adult cells. Interestingly, this applies to all members of the H–2 multigene family^{14,24}, as well as to any other mRNA which could contain the reiterated sequence detected with probe H–2C. Moreover, our results rule out the possibility that H–2 heavy chains are synthesized in EC cells and remain undetected at the cell surface through lack of β_2 m, as reported in several cell lines such as the human Daudi cells²⁵.

To determine whether major rearrangements at the DNA level would account for the absence of H-2 and β_2 m expression in EC cells, we have carried out Southern blots using DNAs extracted from F9, PCC4 EC cells and from 129/Sv liver. DNAs were digested with BamHI and EcoRI, run in 0.7% agarose gels, transferred to nitrocellulose sheets and hybridized with H-2B and β_2 m probes. The multi-band patterns obtained with probe H-2B on EC and liver DNAs are identical as far as the sizes of the bands are concerned; however, differences in the intensity of several bands do exist (Fig. 4). Two major bands were detected when using the β_2 m probe, and their sizes did not change on differentiation (data not shown). These findings confirm the absence of major DNA rearrangements in and around β_2 m and H-2 genes during differentiation 26 .

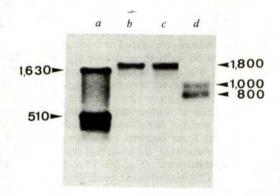

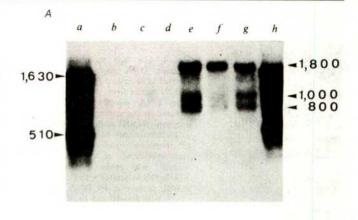

Fig. 2 Poly(A)⁺ RNAs were extracted from adult organs, precipitated with ethanol and isolated by binding twice to oligo(dT) cellulose as described elsewhere³¹. 5 μg of each preparation were subjected to electrophoresis in a 1.1% agarose gel and transferred to nitrocellulose sheets, also as described elsewhere¹⁸. The sheets were prehybridized, hybridized to ³²P-radio-labelled restriction fragments. A, B, C and D restriction fragments (Fig. 1) were polymerized using T4 DNA ligase (Boehringer Mannheim) and then ³²P radiolabelled by nick-translation³² to a specific activity of 2–3× 10⁸ c.p.m. per μg. Each nitrocellulose sheet was hybridized with 10⁷ c.p.m. of each probe for 24 h and then washed as described previously¹⁸. The sheets were then autoradiographed on flash-activated Kodak X-Omat films for 2–14 days depending on experiments, at −70 °C with intensifying screens. Lane a, 2 ng of pBR322 digested by *Hin*fl were hybridized with a pBR322 probe. Lanes b, c, 5 μg of poly(A)⁺ RNA respectively extracted from DBa/2 liver and from 129/Sv liver, spleen and kidney, were hybridized with probe B. Lane d, 5 μg of poly(A)⁺ RNA extracted from liver DBA/2 were hybridized with probe D. (Autoradiographic exposure time 48 h.) In our experimental conditions, 18S rRNA migrates slightly above 1,800 bp (a location corresponding to a size of 1,920 bp DNA).

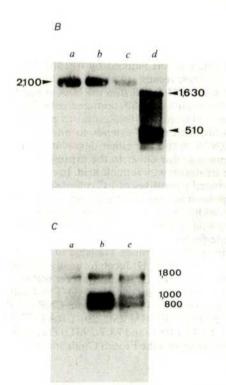

Fig. 3 A, Poly(A)⁺ RNAs were extracted from EC cell lines and used for Northern blotting as described in Fig. 2 legend. Lanes a, h, 10 ng of pBR322 digested by Hinfl were hybridized with a pBR322 probe. Lanes b-d, 5 μg of poly(A)⁺ RNAs respectively extracted from PCC4-aza, F9 and PCC3 EC cell lines, were hybridized with probes B and D. Lanes e-g, 5 μg of poly(A)⁺ respectively extracted from DBA/2 liver, DBA/2 spleen and 129/Sv liver, spleen and kidney, were hybridized with probes B and D. (Autoriadiographic exposure time 48 h.) B, Lanes a-c, 5 μg of poly(A)⁺ RNAs, respectively extracted from PCC3, F9 and PCC4-aza, were hybridized with an actine probe. Lane d, 2 ng of pBR322 digested by Hinfl were hybridized with a pBR322 probe. (Autoradiographic exposure time 48 h.) C, Lane a, 10 μg of poly(A)⁺ RNA extracted from PCC4-aza EC cells. Lane b, 4 μg of poly(A)⁺ RNA extracted from 129/Sv liver, spleen and kidney. The nitrocellulose filter was hybridized simultaneously with B and D probes. (Autoradiographic exposure 24 h.)

It thus seems likely that H-2, H-2-related genes and the β_2 m gene(s), taken here as developmentally regulated genes, are primarily controlled at the level of transcription. These genes belong to different chromosomes (H-2, TL, Qa genes, lie on chromosome 17, β_2 m probably maps on chromosome 2^{27} ; the locations of H-2-related genes are not precisely known). Therefore, no common *cis*-regulatory process could be postulated on a topological basis.

Croce et al.²⁸ published similar but not identical results on F9 EC cells transformed with a plasmid carrying herpes simplex virus type 1 TK gene and SV40 genes²⁹. The expression of H-2

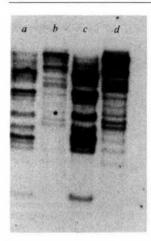

Fig. 4 The high molecular weight genomic DNA was extracted and purified as described previously24 from 129/Sv mouse liver and from F9 EC DNA samples (20 μg) were digested by the appropriate restriction enzymes (BamHI or EcoRI), subjected to electrophoresis in a 0.7% agarose gel, transferred to nitrocellulose sheets and hybridized as described previously24 with probe B. Lanes a-b, 129/Sv DNA digested with BamHI and EcoRI; lanes c-d, F9 DNA digested with BamHI and EcoRI.

and SV40 antigens was induced by treatment of the cells by retinoic acid. Their results are identical to ours concerning the absence of specific H-2 and β₂m mRNAs in nondifferentiated cells, but their results on differentiated cells differ from ours. Croce et al. obtained a hybridization to a smear and not to distinct bands. This smear extends to much lower molecular weight mRNAs, suggesting either degradation or alteration of a normal message due either to the expression of the inserted plasmid or treatment with retinoic acid. In contrast, clonal lines of differentiated derivatives of EC cells display, in our studies, the same pattern as normal differentiated cells. Thus, the pattern observed by Croce et al. might reveal changes in a normal gene expression caused by a non-physiological differentiatory agent or interference with viral genes.

The actine probe was made available to us by F. Brégégère and A. Minty. We thank H. Jacob for many helpful discussions and the gift of EC cells, D. Rocancourt for technical assistance and M. Caravatti for his gift of C17-S1-D-T 984 poly(A)⁺ RNA. This work was supported by grants from CNRS (ER 201, ATP 4246 and 5039), INSERM (SC 20, CRAT 72.79.104) and DGRST (ATP 79.7.0500 and 78.7.2931). The work was carried out in accordance with the French Guidelines for Recombinant Research.

Nuclear localization and DNA binding of the transforming gene product of avian myelocytomatosis virus

Peter Donner, Irene Greiser-Wilke & Karin Moelling

Max-Planck-Institut für Molekulare Genetik, Berlin-Dahlem, 1 Berlin 33, Ihnestrasse 63-73, FRG

Oncornaviruses transform cells either directly through a viruscoded oncogene¹ or, if they lack such a gene, indirectly by promoter insertion²⁻⁴ into the cellular genome and activation of a cellular gene. Both transformation mechanisms ultimately result in abnormally high expression of normal genes. Recently, the activated cellular gene in certain lymphomas4 has been shown to be homologous to the oncogene of an acute avian leukaemia virus, MC29. In MC29 the oncogene is fused to the viral structural gene, gag. The product of this fused gene is a protein of molecular weight 110,000 (110 K)5-7, designated p110gag-myc. We have characterized this protein by using monoclonal antibodies against p19, the N-terminal portion of the gag-myc fusion or 110 K protein and purified it 3,700-fold by immune affinity column chromatography. Immunofluorescence studies and cell fractionation of MC29-transformed fibroblasts indicate that the 110 K protein is predominantly located in the nucleus. Moreover, the purified protein binds to doublestranded DNA. These properties may be related to the role of the protein in transformation.

The MC29-transformed quail embryo fibroblast cell line. MC29-Q8-NP, does not produce virus particles but expresses the transforming protein gag-myc, which is fused to the viral structural gag proteins p19 and p27⁵. The monoclonal antibody against p198 allowed immunoprecipitation of the 110 K protein (Fig. 1A). Superinfection of this cell line with a helper virus, Rous-associated virus RAV-60, resulted in synthesis of viral polyprotein precursors which were about five times more abundant than the 110K protein. RAV-60-infected quail fibroblasts exhibited viral polyprotein precursors but no 110K protein (Fig. Indirect immunofluorescence using the IgG of monoclonal anti-p19 and fluorescein-conjugated anti-mouse IgG9 revealed that the MC29-Q8-NP cells showed a strong nuclear fluorescence (Fig. 2a, d) while the helper virus-superinfected cells showed a predominantly cytoplasmic staining (Fig. 2b). Normal quail embryo fibroblasts did not give rise to a positive fluorescence (Fig. 2c), while predominantly cytoplasmic fluorescence was seen in quail embryo fibroblasts infected with RAV-60 (Fig. 2e) and in the Rous sarcoma virus-transformed cell line R(-)Q, which expresses the transforming protein pp60^{src} and viral polyprotein precursors¹⁰ (Fig. 2f). Therefore, the nuclear fluorescence of MC29-transformed quail fibroblasts seems to be specific for transformation by MC29. All other known oncornaviral transforming proteins were shown to be localized mainly in the cytoplasmic membrane¹¹

To confirm our observation, a cell fractionation from radioactively labelled MC29-Q8-NP cells and RAV-60-superinfected MC29-Q8-NP cells was performed. Nuclei were isolated by hypotonic shock and Dounce homogenization and subsequently stripped by treatment with nonionic detergent12, a procedure which leaves behind a crude chromatin preparation. The soluble fractions were combined and contained endoplasmic reticulum, organelles, cytoplasmic and nuclear membranes and polysomes. The stripped nuclei contained 70% of the 110K protein, while the residual 30% were present in the soluble fraction, which also contained >90% of each of the viral proteins Pr180gag-pol, Pr76gag, p27, Pr92env and gp85. These values were derived from the radioactivity eluted from the various protein bands of the gel shown in Fig. 1B and C and corrected

for differences in volumes. The 110K protein was only detectable in the soluble fraction if 10 times more radioactive material was used (Fig. 1B).

For further analysis the 110K protein was purified from 35S-methionine-labelled MC29-Q8-NP cells by an immune affinity column containing protein A-Sepharose to which monoclonal anti-p19 IgG was covalently coupled in conditions which link the constant region of the IgG molecule to the solid phase 13. The 110K protein was eluted from the column with a buffer of low pH (pH 2) and salt (Fig.3a), conditions which have been applied to purify biologically active human leukocyte interferon 14. Comparison of the radioactive material eluted from the immune affinity column with the total radioactive input indicated a 3,700-fold purification. The eluted 110K protein was precitable by anti-p19 serum, indicating that it was still antigenically active (Fig. 1, slots a, b). The p19-containing viral polyprotein precursors in virus-producing cells were isolated by the identical purification procedure from Rous sarcoma virus-infected chicken embryo fibroblasts (Fig. 3b). Many p19related polyproteins were eluted, the majority of which was represented by Pr76gag, which served as a control for nucleic acid-binding studies described below.

Because the localization of the 110K protein in the nucleus raised the question of whether it interacted with cellular DNA, the purified protein was analysed for its nucleic acid-binding properties in vitro. DNA of a defined size class was preparatively isolated from avian fibroblasts¹⁵, mixed with the ³⁵S-methionine-labelled purified 110K protein and sedimented in a glycerol gradient. In these conditions the 110K protein comigrated with the DNA, whereas without DNA it remained on top of a gradient run as a control (Fig. 4a). To determine whether the nucleic acid-binding property of the 110K protein was attributable to the gag or the transforming protein portion, Pr76gag and p19-related polyproteins were analysed in the same way. These proteins did not bind to the DNA (Fig. 4b), indicating that it is the transformation-specific moiety of the 110K protein which interacts with the DNA.

The nucleic acid-binding property of the 110K protein was also demonstrated by using radioactively labelled DNA to measure the ability of the 110K protein to retain DNA on a nitrocellulose filter in a filter binding assay¹⁶. The 110K but not the Pr76gaag protein allowed the binding of DNA quite efficiently (Fig. 4c). Use of ³⁵S-methionine-labelled proteins enabled us to control the linearity of binding of the protein to

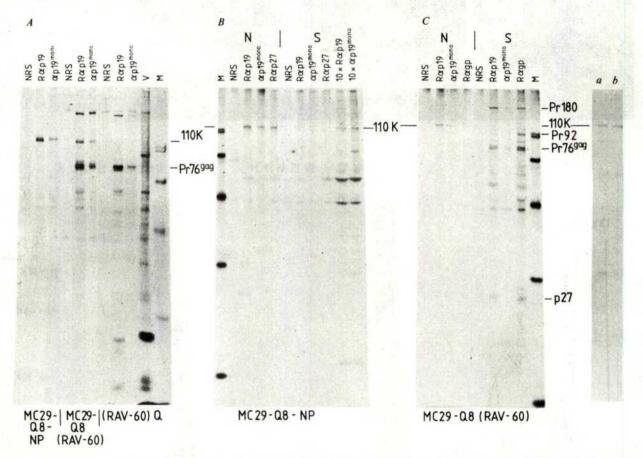

Fig. 1 Distribution of 110K protein in cells and subcellular fractions. *A*, MC29-Q8-NP cells, MC29-Q8 cells superinfected with RAV-60 (MC29-Q8 (RAV-60)) and RAV-60-infected quail fibroblasts ((RAV-60)Q) (3×10⁶ cells each) were labelled with ³⁵S-methionine (250 μCi ml⁻¹) for 4 h, lysed and treated with anti sera and *Staphylococcus aureus*²¹ for indirect immunoprecipitation. The precipitates were analysed on polyacrylamide slab gels and processed for autoradiography²⁰. The sera used were: NRS; normal rabbit serum; Rαp19, rabbit anti-p19; αp19^{mono}, purified IgG of monoclonal antibodies against p19; 5 μl of each serum was used and 10 μg of the IgG. V represents ³⁵S-methionine-labelled RAV-60 virus and M a set of ¹⁴ C-labelled marker proteins (Amersham) (from top) molecular weights of 92.5K (upper band of doublet), 69K, 46K, 30K and 14K. *B*, Isolation of stripped nuclei was performed according to published procedures ¹². MC29-Q8-NP cells (1.5×10⁷) were radioactively labelled with 250 μCi ml⁻¹ of ³⁵S-methionine²⁰ for 4 h and processed immediately. The plates were washed three times with ice-cold phosphate-buffered saline (PBS, 17 mM Na₂HPO₄, 2.6 mM KH₂PO₄ pH 7.4, 120 mM NaCl) and treated with hypotonic buffer (10 mM Tris-HCl pH 7.3, 10 mM NaCl, 1.5 mM MgCl₂) for 40 min at 4°C for lysis. Subsequently the cells were homogenized in a tightly fitting Dounce homogenizer with 10-20 strokes. Release of nuclei was followed by phase contrast microscopy. The nuclei were pelleted at 3,000 r.p.m., for 5 min, and the pellet was resuspended in hypotonic buffer and treated with 1% NP40 and 0.5% desoxycholate (DOC) to strip the nuclei. After mixing on a Vortex for 4 s the stripped nuclei (N) were pelleted (3,000 r.p.m., 5 min). The soluble supernatants (S) were combined and brought up to 50 mM Tris-HCl pH 7.2, 150 mM NaCl, 0.1% SDS, 1% DOC, 1% Triton X-100 (RIPA buffer). The stripped nuclei were suspended in 1 ml RIPA buffer. After incubation for 15 min at 0°C, samples were centrifuged (10,000

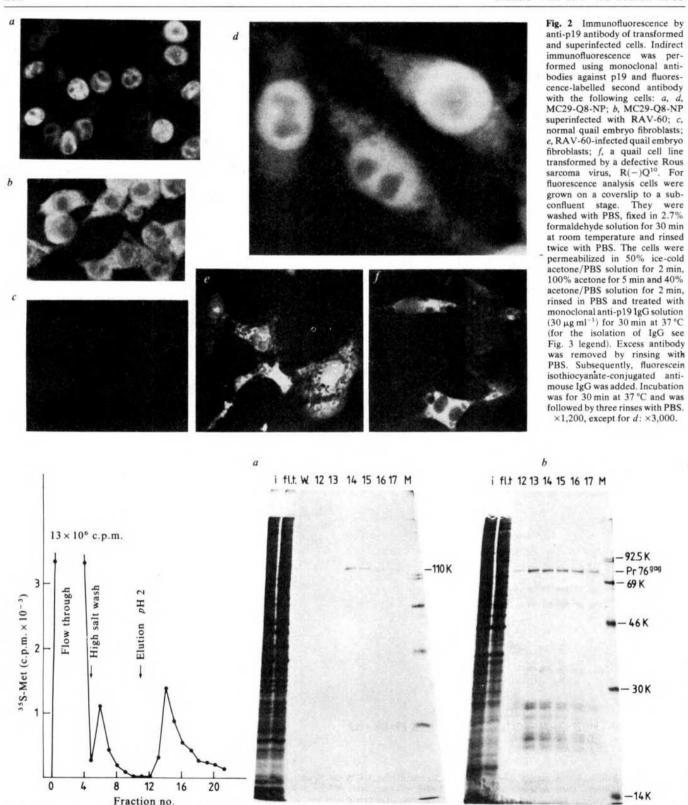

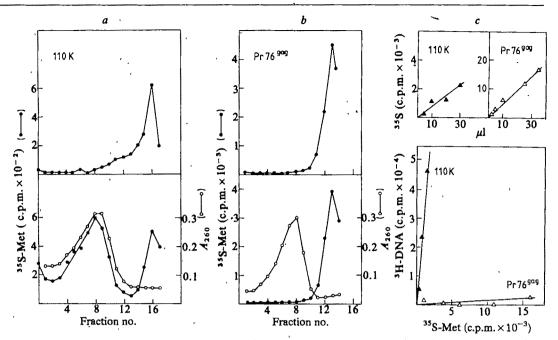

Fig. 3 Isolation of 110K protein from MC29-Q8-NP cells and Pr76^{gag} from virus-producing chicken fibroblasts by immune affinity chromatography. *a*, IgG from monoclonal anti-p19 was purified by protein A-Sepharose column chromatography (Pharmacia) from hybridoma supernatant and eluted with 4 M MgCl₂. The immunoabsorbance column was prepared according to Gersten and Marchalonis¹³: 7 mg of purified anti-p19 IgG were covalently coupled to 1 ml of protein A-Sepharose CL-4B by dimethylsubermidate (30 mg) in 0.1 M borate buffer, *p*H 8.0. Then the column was pretreated successively with 1 ml each of PBS, PBS plus bovine serum albumin (1 mg ml⁻¹), PBS, a lysate of 10⁸ normal quaii methyo fibroblasts, and PBS. For preparation of the cell lysate, 5×10⁷ MC29-Q8-NP cells were labelled with 250 μCi ml⁻¹ of ³⁵S-methionine for 4 h (ref. 20), lysed with 10 ml RIPA buffer in the presence of trasylol (Bayer) and centrifuged at 10,000 r.p.m. at 4 °C for 30 min. The supernatant (12 ml containing 6.4×10⁸ c.p.m.) was then applied to the immune affinity column (200 μl bed volume). The column was washed successively with 5 ml RIPA buffer, 5 ml high-salt buffer (20 mM Tris-HCl *p*H 7.5, 1 M NaCl, 0.5% NP40) and 2 ml PBS before the protein was eluted with a buffer containing 0.1 M citric acid *p*H 2, 300 mM NaCl, 50% ethylene glycol, 0.1% Triton X-100. Fractions of 400 μl were collected, 20 μl of each fraction was counted in a scintillation counter and 50 μl applied to a SDS-polyacrylamide slab gel (10%). In total, 1.8 × 10⁵ c.p.m. were eluted, indicating a 3,700-fold enrichment. The 110K protein-containing fractions were diluted and dialysed overnight against 50 mM phosphate buffer *p*H 6.2, 100 mM NaCl, 1 mM dithiothreitol and 10% glycerol. i, 5 μl of the input (12 ml); fl.t., 5 μl of the flow-through; W, 5 μl of the pooled wash (10 ml); 12-17, eluted fractions; M, ¹⁴C-labelled marker proteins (see Fig. 1 legend). b, The identical procedure was performed with Rous sarcoma virus-infected chicken embryo fibroblast

Fig. 4 Interaction of the 110K protein with DNA. a, DNA was extracted from chicken embryo fibroblasts15 and sheared by pressing it six times through a 21-gauge needle. The DNA was centrifuged through a 10-30% glycerol gradient in a SW41 rotor at 40,000 r.p.m. for 5 h, and the peak fraction was premethionine-labelled dialysed protein from immune affinity column (fractions 14 and 15, Fig. 3a). The protein was mixed with the DNA (50 µg in 50 µl) and meubated at 30 °C for 10 min in 50 mM Tris-HCl pH 8, 100 mM NaCl, 2 mM EDTA buffer. The reaction product was sedimented through a 10-30% glycerol gradient in the same buffer. Centrifugation was in a SW41 Tr rotor at 30,000 r.p.m. for 19 h at 4 °C. 500 µl fractions were collected and 10 µl per fraction was used to measure the radioac-

· ' ' ' ' ' ' _' '

tivity. The DNA content of each fraction was determined by measuring the absorbance at 260 nm. The control gradient contained only the protein and no DNA. b, To analyse the interaction of Pr76^{prac} with DNA, the same procedure was applied. Pr76^{prac} and other p19-related proteins golated by immune affinity chromatography (see Fig. 3b) were dialysed and sedimented in the same conditions as the 110K protein in the absence of DNA. c, Filter binding assay of 110K and Pr76^{prac} proteins and DNA The ability of the purified 110K and Pr76^{prac} proteins (fraction 14, Fig 3a and b) to bind to DNA were analysed using a filter binding assay¹⁶. The incubation mixture (0.5 ml) contained 50 mM Tris-HCl PH 8.0, 2 mM EDTA, 2 µg of sheared ³H-labelled double-stranded DNA from chicken embryo fibroblasts, corresponding to 155,000 c.p.m., and proteins as indicated. After 10 min at 30 °C, the mixture was slowly filtered through a nitrocellulose filter (Selectron, Schleicher & Schuell, type BA85) and washed with 10 ml of the buffer used in the incubation mixture. The filter was pretreated with 0 3 M NaOH for 5 min and washed with H₂O (ref. 22). Binding of the proteins to the filter was controlled by determination of the ²⁵S-methionine radioactivity bound to the filters (top).

the filter (Fig. 4c, top). From this assay it was estimated that $\sim 1~\mu g$ of 110K protein bound to 1 μg of cellular DNA, based on specific activities of 5×10^6 c.p.m. per mg of cellular proteins and 8×10^4 c.p.m. per μg of DNA.

To rule out the possibility that binding of the 110K protein to DNA was a consequence of the stringent elution conditions from the immune affinity column and not a property of the native protein, DNA binding to 110K was analysed by a modified approach. Instead of eluting the protein from the immune affinity column described in Fig. 3, the loaded column was exposed to 3 H-labelled cellular DNA. In these conditions 85% of the DNA was bound to the column and did not elute with 0.6 or 2 M NaCl; only treatment with 1% SDS allowed its elution (Fig. 5a). A subsequent treatment of the column with pH 2 buffer removed the 35 S-methionine-labelled 110K protein. When the column was then analysed in a control experiment for its binding of DNA without the 110K protein, most of the DNA did not bind in these conditions (Fig. 5b).

We describe here for the first time the isolation and characterization of a transformation-specific protein of an acute avian leukaemia virus. It differs from other known oncornaviral proteins¹¹ in its nuclear localization and ability to bind to DNA. None of the gag-related polyproteins shown in Fig. 3b bound to DNA, indicating that DNA binding is probably due to the

transforming part. However, the biological significance of this property is unknown. Furthermore, transformation of fibroblasts analysed here will have to be compared with that of bone marrow cells, the *in vivo* target cells which differ in their transformation parameters¹⁷. The properties of 110K protein—although novel for oncornaviral transformation-specific proteins—closely resemble those of the large T antigen of SV40¹⁸.

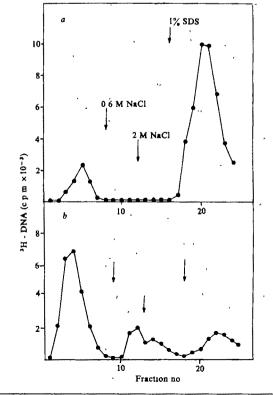

Fig. 5 Interaction of DNA and immune affinity column-bound 110K protein. a, An immune affinity column was prepared and loaded with 35 S-methionine-labelled cellular lysate as described in Fig. 3 legend. Instead of eluting the 110K protein from the column, 3 H-labelled cellular DNA ($^{7.5} \times 10^{5}$ c.p.m., specific activity 105 c.p.m. per μ g) was loaded onto the column. A wash with PBS removed 15% of the DNA from the column. It was then treated with 0.5 ml TE buffer (50 mM Tris-HCl pH 8.0, 2 mM EDTA) containing 0.6 M NaCl and 2 M NaCl, respectively. No DNA was eluted. Only with TE buffer containing 1% SDS, 85% of the total DNA mput radioactivity was recovered. 0.1-ml fractions were collected, 5 μ 1 of each fraction being used to determine the radioactivity. The column was then treated with μ 1 2 buffer to elute the 110K protein as described in Fig. 3a legend. Subsequently the column was rinsed with PBS and used for a control experiment (b). The same amount of 3 H-labelled DNA was applied to the column and treated exactly as described in a. 65% of the input DNA appeared in the flow-through, 25% eluted with 0.6 M and 2 M NaCl and residual 10% with 1% SDS.

Other gag-onc fusion proteins can be isolated in the way described here and their properties compared. Also, the availability of the purified 110K protein will permit polyvalent or monoclonal antibodies to be raised—preferably after removal of the gag portion by p15^{19,20}—so that transformation-specific antibodies will become available.

We thank M. K. Owada, T. Bunte and Erich Lanka for stimulating discussions and cooperation, and Klaus Bister for supplying the MC29-Q8-NP cells.

Spontaneous fragmentation of actin filaments in physiological conditions

Albrecht Wegner

Department of Physiological Chemistry I, Ruhr-University Bochum, Universitaetsstrasse 150, D-4630 Bochum, FRG

Actin filaments have been shown to result from nucleation and consecutive binding of actin monomers to the ends of filaments1. Nucleation is assumed to consist of the aggregation of a few monomers to form a small filament, but apart from the nucleation and the elongation reaction, end-to-end association of filaments has also been reported2. It is not known whether in physiological conditions actin filaments can break spontaneously at subunit contacts along the filament. In view of the possible importance of spontaneous fragmentation in the determination of the length, number and turnover of thin filaments in the cell, I have now studied this reaction by measuring the polymerization kinetics of actin at low total concentrations in physiological conditions (1 mM MgCl₂, 100 mM KCl, 37 °C). Quantitative analysis of the polymerization curves suggests that actin filaments break spontaneously and consequently create more nucleation sites as the reaction proceeds. This explains the autocatalytic nature of the polymerization kinetics.

The polymerization was followed by 90° light-scattering intensity using a Zeiss fluorometer (546 nm). The light-scattering intensity R of long rod-like aggregates such as actin filaments has been shown to be proportional to the concentration of actin filament subunits c_i (refs 3,4).

$$R = a \cdot c_t \tag{1}$$

The constant a was calibrated by measuring the scattering intensity of solutions of known actin filament subunit concentrations. Actin was prepared as described earlier⁴, thereby omitting the modification with N-ethylmaleimide, and the protein was applied to a Bio-Gel P-150 column to remove aggregates. Actin (<10 μM) was dialysed against a buffer containing 0.5 mM ATP, 10 µM MgCl₂, 1 mM dithiothreitol, 200 mg l⁻¹ NaN₃ and 5 mM triethanolamine hydrochloric acid (pH 7.5). The polymerization was initiated by mixing two volumes of dialysed monomeric actin with one volume of a buffer consisting of 0.5 mM ATP, 1.5--6 mM MgCl $_2$, 150--600 mM KCl , $0\text{--}150~\mu\text{M}$ CaCl₂, 0-600 µM EGTA, 10 mM dithiothreitol, 200 mg l NaN₃ and 5 mM triethanolamine hydrochloric acid (pH 7.5). Before mixing, all solutions were centrifuged for 1 h at 100,000g to remove dust and possibly occurring actin polymers. All experiments were performed at 37.1 °C.

The polymerization curves are depicted in Fig. 1. An attempt was made to fit these curves by a simple polymerization model⁴ that takes into account nucleation $(K_N, equilibrium constant)$ for formation of a nucleus from n monomers), association of monomers to the filament ends (k, association rate constant) and dissociation of subunits from the filament ends (k', dissociation rate constant). However, it was not possible to find calculated curves that were in good agreement with measured kinetics (Fig. 1). Particularly at low total actin concentrations, the measured curves are significantly more sigmoidal than the calculated curves.

The long lag phase observed at low total actin concentrations is indicative of an autocatalytic reaction such as self-reproduction of filaments by fragmentation. To test whether the experimental data are compatible with fragmentation of filaments, a kinetic theory can be readily developed by extension of the nucleation elongation model⁴. Filament subunits (concentration c_1) result from binding of monomers (concentration c_1) to the ends of filaments and are consumed by dissociation of subunits from the ends. Hence

$$\frac{dc_t}{dt} = (kc_1 - k')C = (k(c_{tot} - c_t) - k')C$$
 (2)

where c_{tot} is the total actin concentration and C is the concentration of actin filaments. The rate of filament formation by

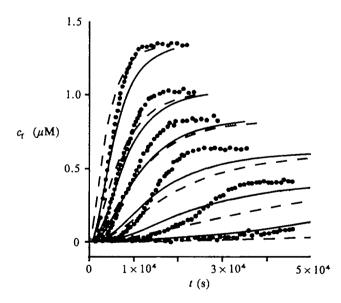

Fig. 1 Time course of the actin filament subunit concentration c_t. Salt concentrations: 1 mM MgCl₂ and 100 mM KCl. ● Measured kinetics, total actin concentrations (µM): 0.41, 0.62, 0.82, 1.03, 1.23 and 1.54; final constant monomer concentration (critical concentration): $\bar{c}_1 = k'/k = 0.21 \,\mu\text{M}$. , Calculated curves; the nucleus was assumed to be a dimer (n = 2) and fragmentation was assumed not to occur; rate parameter obtained by combining equations (2) and (3): $k^2 K_N = 1 \times 10^3 \text{ mol}^{-1} \text{ s}^{-1}$ Calculated curves; the nucleus was treated as a tetramer (n = 4)and fragmentation was assumed not to occur; rate parameter: $k'^2K_{\rm N}=1.1\times10^9\,{\rm mol}^{-3}\,{\rm s}^{-2}.$

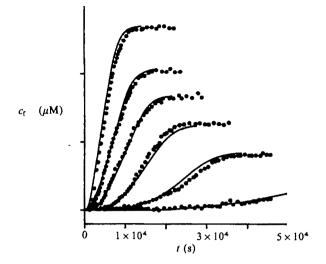

Fig. 2 Time course of the actin filament subunit concentration ct. For salt concentrations and actin concentrations see Fig. 1 legend. , Measured curves. , Calculated curves; the nucleus was treated as a tetramer (n = 4) and fragmentation was assumed to occur; rate parameters obtained by combining equations (2) and (3): $k'^2 K_N = 5.8 \times 10^8 \text{ mol}^{-3} \text{ s}^{-2}$, $k' k_t = 1.7 \times 10^{-8} \text{ s}^{-2}$.

nucleation and fragmentation is given by

$$\frac{\mathrm{d}C}{\mathrm{d}t} = (k(c_{\mathsf{tot}} - c_{\mathsf{f}}) - k')K_{\mathsf{N}}(c_{\mathsf{tot}} - c_{\mathsf{f}})^{n} + k_{\mathsf{fr}}c_{\mathsf{f}}$$
(3)

 k_{tr} is the rate constant of fragmentation at a subunit contact zalong an actin filament. The first term of the kinetic equation (3) represents nucleation from monomers⁴ whereas the second term gives the rate of filament formation by fragmentation. Because of the uniformly double-helical structure of actin filaments the fragmentation reaction is assumed to occur at any subunit contact with the same rate, thereby neglecting end effects. When fragmentation is assumed to occur, polymerization curves can be calculated that reveal a long lag phase at low total actin concentrations and are in good agreement with the measured data (Fig. 2).

Slow isomerization steps in the early phases of polymerization can be excluded as a reason for the lag phase because isomerization steps lead to a lag phase independent of the total actin concentration whereas the experimental curves have increased sigmoidicity only at low total actin concentrations.

Addition of calcium (50 µM) or EGTA (200 µM) or variations in the magnesium (0.5-2 mM) or potassium concentration (50-200 mM) did not significantly affect the shape of the polymerization curves. The experiments suggest that actin filaments can break spontaneously quite independently of the ion concentrations.

The inherent instability of actin filaments resulting in spontaneous fragmentation may provide a further pathway of filament formation in addition to nucleation from actin monomers and growth of filaments induced by other molecules. This reaction may be important in determining the length and the number of filaments in the cell. Recently, several molecules^{5,6} have been reported to cause the conversion of filaments into short fragments by binding to one end of the filaments. The question arises of whether these molecules act by preventing end-to-end association of spontaneously broken filaments or whether they disrupt actin filaments.

The C conformation is a low salt form of sodium DNA

N. J. Rhodes*, A. Mahendrasingam*, W. J. Pigram*, W. Fuller*, J. Brahms†, J. Vergne† & R. A. J. Warrent

Three well-defined conformations have been observed for naturally occurring DNAs in oriented fibres. These have been designated A, B and C and their detailed geometries in a variety of crystalline and semi-crystalline forms determined by X-ray fibre diffraction analysis¹⁻⁵. The C conformation is commonly observed as a low humidity form of the lithium salt3. However, when the counter-ion is Na⁺ rather than Li⁺, previous X-ray fibre diffraction studies^{6,7} have suggested that the C form is at best a poorly favoured conformation. Arnott and co-workers^{6,2} reported that the C form is stable at relative humidities and salt contents which are both intermediate between those which favour the A and B conformations. Zimmerman and Pheiffer9 observed C-like patterns from fibres of Na-DNA immersed in t-butanol/water mixtures. They emphasized that the C form should be visualized as a family of related structures and suggested that continuous smooth transitions occur between the various members of the C family and between the B and C forms. IR linear dichroism studies have shown that a C-like conformation can occur in oriented films of Na-DNA¹⁰ at very low salt contents. Transitions between the A and B forms of Na-DNA depend on the salt content of the fibre and its relative humidity11. Here we describe the conditions for routinely observing the C form of Na-DNA. These are applicable to a wide variety of natural DNAs and to the synthetic polynucleotide poly(dA-dC) · poly(dG-dT).

The DNAs studied were calf thymus, Clostridium perfringens. herring sperm, pollock roe, salmon sperm, Escherichia coli (all from Sigma), SP 15 (from Professor M. Mandel), T2 phage, Micrococcus lysodelkticus (both from Miles), $\phi W-14^{11}$, and poly(dA-dC) · poly(dG-dT). The final stage in the preparation was by either ethanol precipitation from ≤0.1 M NaCl or centrifugation at 50,000 r.p.m. from NaCl as low as 0.001 M. Fibres were drawn from either the precipitate or the concentrated gel and X-ray diffraction patterns obtained at relative humidities from 0 to 98%. The NaCl concentration in a fibre was increased by re-dissolving it in a small quantity of distilled water and then adding to it a small quantity of a standard NaCl solution. A new fibre was pulled from the resulting gel, without loss of DNA. When fibres were made from precipitated material, the piece used was weighed and the DNA in the specimen determined after allowing for water content. For specimens from centrifuged material similar estimates were made using measurements of A_{260} for the original solution and supernatant. Hence, it was possible to calculate the number of Na⁺ and Cl⁻ added per DNA PO₄.

All the Na-DNAs studied could be induced to assume the C form and Fig. 1 shows examples of their diffraction patterns. Where the patterns were sufficiently well defined they were of the hexagonal rather than orthorhombic type, with helical parameters not significantly different from those previously reported³. Conditions were found for which all the DNAs studied assumed the B conformation and also, with the exception of DNA from T2 and SP15, the A conformation. C patterns from the various Na-DNAs were only observed from fibres

containing very little NaCl and in an environment of low relative humidity.

For all DNAs which could assume the A form, fibres giving the C pattern at low humidity exhibited transitions first from the C form to the fully crystalline A form and then from A to the semi-crystalline B form as the relative humidity was increased. Generally, the greater the NaCl content of the fibre the lower the relative humidity at which the A pattern occurred. For the lowest amounts of NaCl, C was usually observed at relative humidities from 32 to 75% but as the NaCl content was increased the upper limit in the relative humidity at which C occurred was reduced until it reached a level when the C pattern was no longer observed. For poly(dA-dC) · poly(dG-dT) this occurred when more than 0.7 Cl ions per DNA PO₄ had been added to the fibre, but for natural DNAs rather less NaCl was required—typically 0.5 Cl⁻ per PO₄. Below 32% relative humidity the X-ray diffraction patterns became much less well defined, indicating a progressive collapse of the structure. As reported previously¹¹, the relative humidity at which the A to B transition occurred decreased with increasing NaCl content. Generally, the transitions $C \rightarrow A \rightarrow B$ were fully reversible as the relative humidity was reduced. However, for poly(dAdC) · poly(dG-dT), with the NaCl concentrations so far studied, the A→B transition was reversible but the C form was only regained if the fibre was re-wetted to form a gel and a new

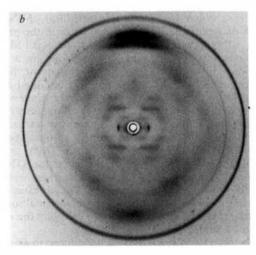

Fig. 1 X-ray diffraction patterns of the C type from calf thymus Na-DNA at 57% relative humidity (a) and Na poly(dA-dC)·poly(dG-dT) at 57% relative humidity (b) (the diffraction ring at 2.81 Å is from NaCl crystallites in the fibre). The two features generally regarded as characteristic of C patterns³ are a peak at ~ 0.1 Å $^{-1}$ on the first layer line and strong diffraction close to the meridian on the eighth layer line. The peaks on the eighth and ninth layer lines in b are particularly well resolved.

fibre drawn. For DNAs which undergo the $C \rightarrow A \rightarrow B$ transitions we have observed patterns which are mixtures of A and C and of A and B. DNA from T2 and SP15 underwent a transition from C to semi-crystalline B with increasing relative humidity.

These results establish the C form as a major conformational possibility for the DNA double helix in biological environments. In contrast to previous work, we have shown that there is no difficulty in inducing Na-DNA to assume the C conformation if both the water content and the level of NaCl in the fibre are sufficiently low. *In vivo*, DNA can be expected to occur predominantly either as the sodium salt or in a state where the Na⁺ ions are displaced by basic groups such as polyamines and lysine and arginine side chains in proteins. Situations can therefore be envisaged in which the conformation of an active region of DNA is controlled by changes in its hydration and the concentration of Na⁺ and Cl⁻ ions in its vicinity.

Earlier reports suggested that the C form of DNA was a variant of the B conformation, with ready transition between the two forms. While such a transition is observed for Li-DNA, in this study of Na-DNA the C → B transition passes through an intermediate A conformation except for those DNAs that do not assume the A form. In contrast to the earlier claim⁶ that at low hydration the NaCl content of fibres of Na-DNA which gave the C form was intermediate between those appropriate for observing the A and B forms, we find that C is favoured by NaCl contents lower than those which favour A. Our view of the A form as an intermediate between the C and B forms of Na-DNA is based on two distinct sets of observations. First, the $C \rightarrow A \rightarrow B$ transitions occur as a function of relative humidity for fibres containing small amounts of NaCl. Second, the $C \rightarrow A \rightarrow B$ transitions occur at a fixed relative humidity (say 57%) as the NaCl content of a fibre is raised.

A striking feaure of this study is the wide range of natural DNAs for which the C form was observed, particularly for DNAs with a G+C content of 31-72%, in agreement with IR studies10. Perhaps of even greater significance, the C form was observed for three DNAs (\$\phi\$W-14, SP15, T2) in which a substantial fraction of the nucleotides were extensively modified12-14. The observation of the C form for this very wide range of natural DNAs suggests it is a structure sufficiently favoured stereochemically for it not to be destabilized by substantial changes in either its charge distribution or the addition of bulky groups. We did not observe the A form for T2 DNA, in accord with earlier studies which suggested this was a consequence of glucosylation of a large fraction of the cytosine residues15. That report also suggested that at low humidity T2 DNA adopts a novel conformation, the T form. In view of our observation of the C form as a low humidity conformation of T2 DNA and because the helix pitch and overall intensity distribution reported for the T form are broadly similar to those which characterize C patterns, we believe that the T form is a close relative, if not a member, of the C family of structures.

The various synthetic polynucleotides exhibit much more variety in the conformations they assume than do natural DNAs8. We have therefore concentrated here on the occurrence of the C conformation for the sodium salt of naturally occurring DNAs. However, we have also studied the synthetic polynucleotide poly(dA-dC) · poly(dG-dT) as an example of DNA with an 'average' nucleotide composition but a highly regular base sequence. Although the C form is also observed for fibres of this DNA containing low amounts of salt at low relative humidities, these fibres differ from those of natural DNAs in the irreversibility observed in the C→A transition. This is reproducible, having been observed for a number of different fibres and also be re-wetting the same fibre. This unusual behaviour of poly(dA-dC) · poly(dG-dT) may be a consequence of its particular nucleotide sequence, resulting in significantly different base-stacking contributions to the conformational energy, or to different patterns of solvent interactions around the DNA.

Transfection of cells from a xeroderma pigmentosum patient with normal human DNA confers UV resistance

Toshiya Takano, Makoto Noda* & Taka-aki Tamura

Department of Microbiology, Keio University School of Medicine, Shinjuku-Ku, Tokyo-160, Japan

Xeroderma pigmentosum (XP) is a human genetic disorder characterized clinically by extreme photosensitivity of the skin and eyes and a high incidence of skin cancer. Cell lines derived from XP patients are very sensitive to UV irradiation, and it is thought that the biochemical lesion responsible for this sensitivity is a defect in excision repair of UV-induced DNA damage1. We report here that transfection of cells from an XP patient with DNA from normal human cells can produce cells resistant to UV damage. The resistant cells have presumably acquired a gene conferring UV resistance; this study represents the first step towards the isolation and characterization of the gene.

Skin fibroblasts of a XP patient, XP20S, were transformed by simian virus 40 (SV40) and established as a permanent cell line, XP20S(SV), by Takebe et al.2. XP20S belongs to the complementation group A and shows an extremely low level of unscheduled DNA synthesis after UV irradiation². XP20S(SV), which has the characteristics of a cultured XP cell as well as those of the parental skin fibroblasts (it was highly UV-sensitive), was used as the transfection recipient.

High-molecular weight DNA was extracted and purified from human cultured cells or from Escherichia coli K-12 by sodium lauryl sulphate-phenol treatment after digestion with pronase E and ribonuclease (ref. 3); 10-30 μg of each DNA were transfected to 7×10⁵ cells of XP20S(SV) using a modification of the calcium phosphate precipitation method of Wigler et al.4. The transfected cultures were then irradiated with UV light and the UV-resistant (UV') cells were scored by colony formation. The transfection and selection of UV cells are described in Table 1 and the results are shown in Table 1a. No colonies were detected after mock transfection ('control' in Table 1a), or after transfection with the self DNA of XP20S(SV) or with E. coli DNA. UV colonies were detected in the cultures transfected with DNAs from human cell lines of rhabdomyosarcoma, A204 (ref. 5), and embryonic lung fibroblasts, MRC-5 (ref. 6), the response being relatively dose dependent. The cells isolated from 10 individual colonies per dish showed UV-resistance equal to that of the DNA donors, A204 and MRC 5. Figure 1 shows the UV sensitivity of the transformed XP20S(SV) cells. However, note that 3-6% of the colonies were very small and consisted of <10 individual cells. The cells from these minute colonies did not survive after colony isolation, and seemed to

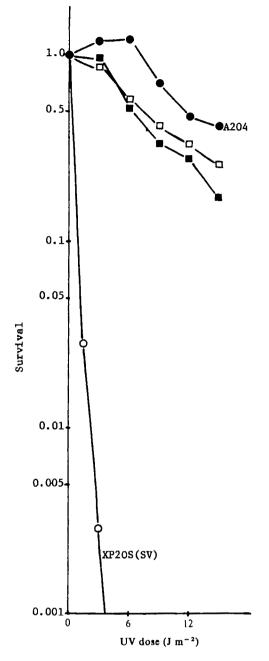

Fig. 1 UV-sensitivity of the transformed XP20S(SV) clones \Box , XP UV^r clone, 1; \blacksquare , XP UV^r clone 2), and the parental (O, XP20S(SV)) DNA donor cells (0, A204). In the experiment shown in Table 1a, colonies were isolated and 2×10^5 cells per colony were plated out in a 60-mm Petri dish, then irradiated with various doses of UV light from the bottom of the dish. The irradiated cells were cultured in the growth medium at 37 °C for 5 days, then the numbers of surviving cells were determined after trypsinization and Trypan blue staining. Results shown for XP UV clones 1 and 2 are typical of the cells of two representative colonies from the culture transfected with A204 DNA (20 µg per dish).

be practically UV-sensitive as were most of the recipient cells. Such minute colonies were detected neither in the mock infection nor in the dishes transfected by self and E. coli DNAs, which means that all the UV-sensitive XP cells were killed and UV transformants alone were detected in the experimental conditions used. The activity transforming the XP cell to UV was carried on the DNA molecules introduced into the transformed cells, because after treatment of A204 DNA with DNase I, there were virtually no UV^{r} transformants (Table 1a).

The frequency of the transformed UV colonies was 1.6-4.1 per µg DNA, whereas Wigler et al.4 described a transformation frequency of ~10 colonies per 20 µg of DNA for the thymidine kinase and adenine phosphoribosyltransferase genes. The higher transformation frequency in our study seemed to be due to cell growth during the 6-day incubation and to re-plating of the cultures before selecting the UV colonies. The numbers of cells in the transfected cultures increased ~4-5 times during the incubation and the generation time of XP20S(SV) was ~26 h in the culture conditions used. Therefore, the initial transformation frequency of XP20S(SV) to UV seems to agree with that obtained by Wigler et al.⁴. The UV-sensitive phenotype of XP20S(SV) was stable; we have never detected any UV colonies in control cultures (untreated) in the experimental conditions used. Together, these results demonstrate that the UV-resistance in transformants is derived from the donor DNA and is not due to reversion of the recipient cell.

It was of interest to determine whether XP20S(SV) could be transformed with DNA which had previously been digested with restriction endonucleases. This would be useful with regard to cloning the gene which renders the XP cell UV-resistant. We therefore analysed the sensitivity of the transforming activity of A204 DNA digested with various restriction enzymes recognizing different hexanucleotide sequences at their

Table 1 Transformation of XP20S(SV) cells to UV-resistance by DNA transfection

Donor DNA	Amount of transfected DNA per dish (µg)	DNA digestion before transfection	UV-resistant colonies per 7×10 ⁵ recipient cells

Control	-	-	0

The recipient cells, XP20S(SV), were plated at 7×10⁵ per 60-mm Petri dish. The next day, DNA from each donor cell was transfected by the procedure described elsewhere4. After 6 h incubation with the DNA-calcium phosphate precipitates, the cells were treated with 10% dimethyl sulphoxide in HBS4 for 30 mm at room temperature. Then the cells were washed once with HBS and incubated in Dulbecco's modified Eagle's minimum essential medium (Gibco) supplemented with 10% newborn calf serum (Mitsubishi Kasci Industrials) at 37 °C for 6 days. The culture medium was changed once a day. After incubation, the cultures were each trypsimzed and subdivided into four 60-mm Petri dishes (Lux, no. 5213). The next day, the cells were rinsed twice with HBS and dried by keeping the dishes up-side down until the cells showed hardly any damage that could be observed during the subsequent incubation. They were then irradiated with UV light from both the top and bottom of the dishes, at 23 and 2.8 J m⁻², respectively. The irradiated cells were incubated in the growth medium at 37°C for a further 6 days then the cultures were again irradiated with UV light at 1.5 J m⁻² from both sides of the dishes, by the procedure described above After incubation in the growth medium for 2 weeks surviving colonies were scored after formaldehyde fixation and staining with Giemsa. The values shown are the averages of results from five independent experiments b, A204 DNA was digested with restriction enzymes (Takara Shuzo or New England BioLabs); 2 units of enzyme per µg DNA, at 37 °C for 4 h Complete digestion of DNA samples with these enzymes was monitored by adding a small amount of bacterrophage \(\lambda\) DNA to an aliquot of each reaction mixture, and analysing the digestion products by gel electrophoresis. The cleaved DNA samples were precipitated with 70% ethanol, dissolved in a small amount of 10 mM Tris-HCl, 1 mM

EDTA pH 7 2, and transfected as described above.

* The DNA was treated with 1 mg ml⁻¹ pancreatic DNase I (Sigma, type I) in 10 mM Tris-HCl, 5 mM MgCl₂ pH 7.2 at 37 °C for 60 min and then transfected.
† Number of minute colonies detected (see also Fig. 2) in which cells did not survive after colony isolation.

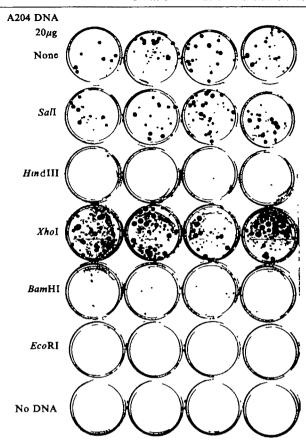

Fig. 2 Petri dishes containing the UV^r colonies detected in the experiments shown in Table 1b. The four dishes in each row were derived from one transfected culture. The restriction enzymes used to digest the transfecting DNA are indicated at the left-hand side.

cleavage sites (see Table 1b and Fig. 2). SalI and XhoI raised the transformation efficiency whereas HindIII, BamHI and EcoRI removed the transforming activity. On the other hand, considerable numbers of minute colonies were detected in the cultures treated with BamHI- and HindIII-digested DNAs; these digested DNAs seemed to raise slightly the UV-resistance of the recipient cell, possibly by abortive transformation. However, we were unable to characterize further the cells in these minute colonies because they did not survive after colony isolation.

The UV-resistant XP20S(SV) cells transformed by both high-molecular weight and restriction endonuclease-cleaved DNA from A204 and MRC-5, showed stable UV phenotypes during passage in culture; we found no revertants that were highly sensitive to UV irradiation.

These results suggest that the DNAs of non-XP human cells contain a gene(s) which confers the UV phenotype on the XP cell, and which carries the BamHI, EcoRI and HindIII sites. SalI and XhoI cleave only outside the functionally important regions of the gene. The gene is not neccessarily the wild-type counterpart of the defective gene in the XP cell, but it could be any gene which can suppress the UV-sensitive phenotype of the XP cell. We are now cloning the DNA sequences carrying the transforming activity using the selection of UV transformants described in this study.

We thank Dr Hiraku Takebe for supplying XP20S(SV) cells. This work was supported by grants-in-aid from the Japanese Ministry of Education, Science and Culture.

Regulation of DNA ligase activity by poly(ADP-ribose)

Debbie Creissen & Sydney Shall

Cell & Molecular Biology Laboratory, University of Sussex, Brighton, Sussex BN1 9QG, UK

Nuclear ADP-ribosyl transferase (ADPRT)1,2 catalyses the transfer of ADP-ribose from NAD+ to chromatin proteins to form mono-, oligo- and poly(ADP-ribose)-modified chromatin proteins3-7. The enzyme is entirely dependent on DNA for activity⁸ and is activated by nicks in the DNA⁹⁻¹¹. Both radiation and alkylating agents deplete cells of NAD which is used to make (ADP-ribose), (refs 1, 2, 12, 15-17), and this depletion is prevented by inhibitors of ADPRT 13,15,18-25. ADPRT inhibitors also retard DNA strand-rejoining after damage^{1,2,26,27}, and potentiate the lethality of DNA-damaging agents^{1,2,28}. N-methyl-N'-nitro-N-nitrosoguanidine, an alkylating agent, transiently increases intracellular (ADP-ribose)_ over 100-fold¹⁷. These data suggest that (ADP-ribose), blosynthesis is necessary for effective repair of some types of DNA damage1. The question remains of which step in DNA repair requires ADPRT activity. The enzyme inhibitors do not prevent incision events^{1,2,27} nor do they inhibit repair replication² Here we describe experiments which support the hypothesis that ADP-ribosylation activates DNA ligase activity. We suggest that ADPRT has a general function in the control of the breaking and rejoining of DNA.

Mammalian cells possess two forms or species of DNA ligase, which have been chromatographically separated³²⁻³⁹. DNA ligase I seems to be involved mainly in replication, while DNA ligase II may be a repair enzyme^{32,33,37-44}. DNA ligase activity may be extracted from cells with 0.5 M salt and Triton X-100, the enzyme activity being reasonably reproducible. In both control cells and cells treated with the monofunctional alkylating agent dimethyl sulphate, the maximum amount of enzyme activity is extracted by 300 mM KCl. Doubling the salt concentration to 600 mM does not extract any further enzyme activity. The enzyme activity may be estimated by measuring the amount of ³²P-5'-phosphate in nicked DNA that becomes inaccessible and therefore resistant to alkaline phosphatase because the DNA ligase activity has converted the 5'-phosphate -to a 3',5'-phosphodiester. We found that on exposure of mouse leukaemic L1210 cells to dimethyl sulphate, the total DNA ligase enzyme activity increased ~2.3-fold (Table 1).

This increase in enzyme activity was prevented by all classes of ADPRT inhibitor, indicating that it is a consequence of ADPRT activity (Table 1). The specificity of the ADPRT inhibitors is indicated by the inability of their non-inhibitory analogues, aminobenzoic acid and nicotinic acid, to prevent the enzyme stimulation (Table 1). Treatment of cells with ADPRT inhibitors does not inhibit the basal DNA ligase activity or the basal or stimulated ligase activity when present in the ligase assay (data not shown).

Again, the stimulating effect on DNA ligase activity of prior exposure of the cells to the alkylating agent is seen following purification of the enzyme by ammonium sulphate precipitation followed by successive chromatography on phosphocellulose and hydroxylapatite columns (Fig. 1). The total recovered enzyme activity of the DNA ligase peak eluting from the phosphocellulose column increased from 3.05 to 5.42 pmol min⁻¹. Hydroxylapatite chromatography of the DNA ligase peak from the phosphocellulose column shows that ligase II is the enzyme predominantly responsible for the increase in activity (Fig. 1). Whereas the ligase I activity eluting from the hydroxylapatite column increased from 1.90 to 2.40 pmol min⁻¹, that of DNA

ligase II increased from 1.27 to 6.20 pmol min⁻¹, a fivefold increase.

An antiserum has been described by Soderhäll and Lindahl³³ that specifically inhibits DNA ligase I from calf, human, rabbit and mouse tissues but does not affect DNA ligase II from the same sources to a detectable extent. We found that this antiserum, at a 1:8 dilution, inhibited our DNA ligase I enzyme activity (see Fig. 1) by 95% but inhibited ligase II enzyme activity (see Fig. 1) by only 11%, which we attribute to contamination of the ligase II peak by some ligase I material. We conclude that our two ligase enzyme activities are identical to those described by Soderhäll and Lindahl³³.

The fact that we used a high salt concentration means that the increase in ligase II activity is probably not due to differential extraction. This possibility is further excluded by the data in Fig. 1 which show that the specific enzyme activity (units of enzyme activity per unit protein) increases sevenfold on exposure to dimethyl sulphate.

We next investigated whether the blocking effect of these ADPRT inhibitors on dimethyl sulphate-stimulated total enzyme activity was specific for DNA ligase II activity. We treated two sets of cells with 300 μ M dimethyl sulphate, one set being simultaneously exposed to 5 mM 3-aminobenzamide, then extracted and partially purified the DNA ligase activities as described earlier. Again, dimethyl sulphate increased the DNA ligase II activity (Fig. 2a). However, this increase did not occur when 3-aminobenzamide was present (Fig. 2b).

One possible explanation of the above results is that DNA ligase II itself, a closely associated protein or some other

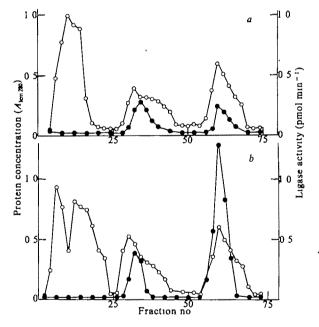

Fig. 1 Increase in DNA ligase II activity after exposure of L1210 cells to dimethyl sulphate. The cells $(100\,\mathrm{ml},\,5\times10^5~\mathrm{cells~ml^{-1}},\,\mathrm{for~each~experiment})$ were incubated for 1 h with or without 300 $\mu\mathrm{M}$ dimethyl sulphate. Salt extracts were prepared as described in Table 1 legend. Ammonium sulphate was added to 75% saturation. The precipitate was collected, redissolved in 15 mM potassium phosphate buffer pH 7.2 and dialysed against the same buffer overnight. A column of phosphocellulose (1.25 \times 7 cm) pre-equilibrated with 15 mM potassium phosphate buffer pH 7.2 was loaded with the dialysed material and washed with 4 ml 15 mM potassium phosphate buffer pH 7.2. Elution with 800 mM NaCl, 15 mM potassium phosphate buffer pH 7.2 continued until no more protein was detected in the cluant. Fractions of 1.0 ml were collected and assayed for DNA ligase activity as described in Table 1 legend. The enzymatically active fractions from the phosphocellulose columns were pooled and loaded directly on to columns of hydroxylapatite $(1.0\times3\,\mathrm{cm})$ pre-equilibrated with 15 mM potassium phosphate buffer pH 7.2. Stepwise elution was carried out with increasing concentrations of potassium phosphate buffer pH 7.2; 1 ml 15 mM, 4.0 ml 50 mM, 5.0 ml 140 mM, 5.0 ml 400 mM. Aliquots (200 µl) were collected and assayed for protein concentration and DNA ligase enzyme activity. O, Protein concentration (A_{280} absorbance units); \bullet , DNA ligase activity (pmol min⁻¹). a, Cells not treated with dimethyl sulphate, b, cells exposed to 300 µM dimethyl sulphate for 1 h

Table 1 Stimulation of DNA ligase activity by an alkylating agent, and its prevention by inhibitors of ADPRT

Mouse lymphoblastic leukaemia cells (L1210 cells) $(5 \times 10^5 \text{ cells ml}^{-1})$ were treated with $300~\mu M$ dimethyl sulphate for 1 h in the presence or absence of the inhibitors (5 mM) or their analogues (5 mM). DNA ligase activity was then extracted from the cells. In control experiments the cells were exposed to the inhibitors or analogues, but were not treated with dimethyl sulphate. The cells were centrifuged and then washed twice with phosphate-buffered saline. The cell pellet was then resuspended in 1/10 the original volume of extraction buffer at 0 °C. The extraction buffer consisted of 500 mM KCl, 20 mM Tris-HCl pH 7.5, 0.5% (v/v) Triton X-100. The cell pellet in the extraction buffer was sonicated twice in an MSE 150-W sonicator for 15 s each time. The enzyme extract was recovered by centrifugation at maximum speed in an Eppendorf microcentrifuge. The supernatant contained the DNA ligase activity; this supernatant was dialysed overnight against 20 mM Tris-HCl pH 7 5, 1 mM mercaptoethanol. DNA ligase activity was estimated with ³²P-5'-phosphate DNA as substrate, prepared according to ref. 45. The DNA ligase assay measures the rate at which ³²P-5'-phosphate becomes inaccessible to alkaline phosphatase because of DNA ligation. The enzyme assay mixture (200 µl) contained 75 mM Tris-HCl pH 7.5, 15 mM MgCl₂, 200 µM ATP, 2 mM dithiothreitol, 20 µg bovine serum albumin, 20 pmol ³²P-5⁷- phosphoryl DNA (1,000 c.p.m. pmol⁻¹), 100 µg ml⁻¹ protein from the enzyme extract. The assay mixture was incubated at 30 °C for 30 min. The reactions were stopped by the addition of 5 μ mol EDTA and 15 μ l 1.0 M Tris-HCl pH 8.5 at 0 °C. The ³²P-phosphate that had become resistant to alkaline phosphatase was estimated according to the procedure described by Weiss et al.*6. One unit of DNA ligase activity catalyses the conversion of 1 pmol of ³²P-5'-phosphate to phosphatase-resistant material in 1 min in the above conditions. The DNA ligase assay is linear with time at least up to 60 min, regardless of whether the cell extracts have been exposed to dimethyl sulphate. Values in parentheses indicate the number of times each experiment was performed. All enzyme activities are expressed relative to the activity in cells not exposed to dimethyl sulphate, inhibitors or their analogues.

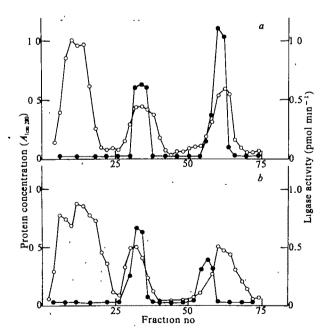

Fig. 2 3-Aminobenzamide prevents the increase in DNA ligase II activity observed after exposure of L1210 cells to dimethyl sulphate. The cells (100 ml, 5×10⁵ cells ml⁻¹, for each experiment) were incubated for 1 h with 300 µM DMS. One set of cells was treated simultaneously with 5 mM 3-ammobenzamide. Salt extracts were prepared as described in Table 1 legend and partial purification of DNA ligases I and II was carried out exactly as described in Fig. 1 legend. O, Protein concentration (A₂₈₀ absorbance units), •, DNA ligase activity (pmol min⁻¹). a, DNA ligase from cells exposed to 300 µM DMS, b, DNA ligase from cells exposed simultaneously to 300 μ M DMS and 5 mM 3-amihobenzamide.

DNA-binding protein is ADP-ribosylated. Preliminary experiments indicate that when permeabilized cells are incubated with ³H-NAD, a specific precursor of (ADP-ribose)_n, a peak of radioactivity co-migrates with the DNA ligase II activity on a hydroxylapatite column.

Thus, we observe that alkylation damage increases DNA ligase activity, predominantly that of DNA ligase II, the presumed repair enzyme. This increase in activity is totally

prevented by inhibiting (ADP-ribose), biosynthesis.

(ADP-ribose), biosynthesis is required for effective DNA excision repair of some types of DNA damage1, while ADPribose is required neither for the incision events^{1,2,28} nor for repair replication³⁰⁻³². We propose that (ADP-ribose), biosynthesis is required for effective DNA excision repair because it is necessary for efficient ligation. The nuclear ADPRT enzyme is stimulated by breaks in the DNA and subsequently stimulates their ligation. However, we suggest that (ADP-ribose), may have a more general role than that of DNA repair, in that it may be sensitive to breaks and regulate subsequent DNA ligation in DNA recombination, sister chromatid exchanges, gene rearrangements, transpositions and cell differentiation which may involve such changes in DNA structure.

This work was supported by the MRC, the SERC and the Cancer Research Campaign. We thank all our laboratory colleagues for constructive help and advice, and Dr S. Soderhäll and T. Lindahl for giving us their specific antiserum against DNA ligase I.

BOOK REVIEWS

From China with love

J.D. Bjorken

In the spring of 1979 T.D. Lee visited China and within the span of seven weeks delivered a remarkably intense set of lectures on elementary particles and statistical mechanics. The number of lecture hours averaged about three per day, seven days a week, and the size of the audience exceeded 900. Lee reports that "...it was very lively. My vocal chords, however, had problems afterward". Parts of the lecture notes have been published in Chinese and the particle physics portion has evolved into this volume.

It is an especially propitious time for such a course to appear. Because of the recent progress in understanding the nature of the fundamental quark and lepton constituents of matter and of the forces they exert on each other, we now are entering what should be a golden age of pedagogy. A few good texts have appeared and more are on the way. The ideal one is yet to be written. But Lee's lectures, as one might anticipate, set a towering standard of excellence. Within 820 pages of lucid text lie most of the important topics in elementary particle theory.

The central element of the new pedagogy is the belief that the strong and weak forces are described by generalizations of quantum electrodynamics called nonabelian gauge theories. A good understanding of this subject requires mastery of a high level of theoretical formalism. This is not easily found in older texts. Lee's lectures help to bridge the gap between the old and the new, concentrating on the theory of the strong force, called quantum chromodynamics or QCD.

But physical insights have not been sacrificed for formalism. The main physical features of the QCD picture of the interquark force are that it is relatively weak at short distances, and that at large distances it confines quarks — that is, only certain colour-neutral combinations of quarks and their antiparticles can exist in isolation. Lee beautifully elucidates these concepts, albeit with considerable subjectivity on the confinement question. At present, the confinement problem is not closed. There are several approaches extant, such as lattice QCD, instantons and string models. Only one approach, which makes an analogy of the QCD vacuum state with a perfect diaelectric medium, is developed in the book. This reflects Lee's current research interests, and is a characteristic of the lectures. They are selective, not encyclopaedic.

The weak - or, better, electroweak -

Particle Physics and Introduction to Field Theory. By T.D. Lee. Pp.865. ISBN hbk 3-7186-0032-3; ISBN pbk 3-7186-0033-1. (Harwood: 1981.) Hbk \$59.50, Dfl.170; pbk \$19.50, Dfl.60.

force is now also generally believed to be described by a non-abelian gauge theory. Lee's lectures emphasize the older phenomenological foundations, although the prevailing SU(2) & U(1) "standard model" is given a spare but reasonable and up-to-date treatment. Here the computational technology might have been carried further. The physics might have been as well: there is no discussion of the ideas of the grand unification of strong, weak and electromagnetic forces, a topic now inspiring a considerable amount of experimental and theoretical work.

An important link between experiment and the basic gauge-theory concepts is the so-called quark-parton model. This is a simple manifestation of the idea that point-like quark constituents reside within nucleons and other hadrons. The quark-parton model is also an element of the new

pedagogy — one which is simple to apply and of great usefulness. It is a good way to learn a lot of physics easily and quickly. Lee develops it well, with relevant examples worked through in physically transparent ways.

But the core of Lee's lectures lies not in the new pedagogy, but the old. There is a concise introduction to quantum field theory, followed by an extended, masterful and definitive section on symmetry principles and the associated conservation laws. This leads to a full discussion of the neutral kaon system — that glory of wave mechanics and source of so many of our deepest insights into nature.

This volume will serve superbly as a comprehensive course in elementary particle theory at the advanced graduate-school level. It is possible to differ with Lee on questions of balance and of selection of material. But the pages are filled with his unique insights, pedagogical clarity and thoroughness. The book is a treasure.

A cooperative venture in soil science

Harry Vine

Characterization of Soils in Relation to their Classification and Management for Crop Production: Examples from Some Areas of the Humid Tropics. Edited by D.J. Greenland. Pp.446. ISBN 0-19-854538-X. (Clarendon/Oxford University Press: 1981.) £35, \$74.

This volume is, with a few added contributions, the report of a "bench-mark soils" project which was based at the International Institute for Tropical Agriculture (IITA) at Ibadan, Nigeria. The core of the book, then, consists of detailed studies of 38 Nigerian soil profiles, in which about 20 specialists in soil science took part.

A major aim of the project was "to provide data that might enable existing soil classification systems used within the tropics to be improved"; this related especially to the American system, which was developed through successive Approximations to the massive handbook, Soil Taxonomy, issued by the United States Department of Agriculture in 1975. The profiles are discussed from this point of

view by F.R. Moormann, who points out a number of difficulties in the published scheme for tropical soils, particularly with regard to weatherable sand-size minerals and to the relative importance of the composition of the clay fraction and evidence of its movement in the profile. A fundamental contribution to the characterization of such soils is made by A.J. Herbillon in a review in which he examines both materials and dynamics.

Underlying the work on this range of profiles was the need, in the Farming Systems Programme of IITA, to discern more definitely what measurable properties of humid tropical soils may be relevant to maintenance of fertility in intensified arable cropping, efficient use of fertilizers and avoidance of erosion. In their review chapter, B.T. Kang and R.L. Fox aptly refer to "misconceptions" that these soils "are quite infertile and have management problems which are encountered nowhere else". On phosphate fixation problems, greatly exaggerated in textbooks, good progress is reported by

P.H. Le Mare, who used isotopicallylabelled phosphate in distinguishing strong bonding from exchange-adsorption in laboratory studies of the soils.

Tropical ecosystems have been described as "fragile", particularly in semi-arid regions. D.J. Greenland writes here and elsewhere about "fragile" tropical soils, using the term in a literal sense, implying that particular properties of the soils (not the intensity of the rainfall) were responsible for a tendency to high rates of erosion. Clearly almost all the bench-mark soils, except those of the amphibolite area, can have little stable structure in the topsoil, being sandy loams; but as the sand is medium to coarse the infiltration rate remains fairly high, and run-off and erosion need not be intense. In this connection, some years ago the IITA group devised a system of no-tillage, which involved mulching with plant material, applying herbicides and omitting the yam crop which is important locally. In advocating this they may have been too greatly influenced by the amount of erosion that occurred on experimental plots under rather absurd methods of cultivation; planting on ridges with cross-bars, as on older stations in Nigeria, would have been a better yardstick.

It is also unfortunate that despite the long-term prospects for cattle, with diseases being brought under control, animal husbandry and therefore alternation of arable crops with grass-legume mixtures — which do well in southern Nigeria - were not considered in the Farming Systems Programme. Consequently one of the most interesting features of this book is the inclusion of a long chapter by P.A. Sanchez, "Soil Management in the Oxisol Savannahs and Ultisol Jungles of Tropical South America". Sanchez summarizes much of the very effective work on the characterization of the soils of these regions and also discusses the field experiments at Brasilia and at Yurimaguas and Pucallpa in Peru. Management of cleared land, with lime, fertilizers, legumes and grass, along lines very similar to those appropriate to the south-eastern USA, has been shown to be successful, whereas it was at the stage of clearance that disastrous erosion could occur; on this evidence, Sanchez' recommendation is that clearance should be carried out gradually by slash-and-burn methods.

As A.J. Smyth says in his foreword, Characterization of Soils amply demonstrates the rewards of collaborative research on tropical soils. However readers would be well advised to study it in conjunction with Sanchez' outstanding textbook, Properties and Management of Soils in the Tropics, published by Wiley in 1976.

Harry Vine, who has worked as a soil specialist in Nigeria, was formerly Senior Lecturer in the Department of Geography at the University of Leicester.

The ins and outs of food production

K.L. Blaxter

Biological Efficiency in Agriculture. By C.R.W. Spedding, J.M. Walsingham and A.M. Hoxey. Pp.383. ISBN 0-12-656560-0. (Academic: 1981.) £18.40, \$38.

AGRICULTURE is a very complex undertaking. It involves the use of plants and animals and the deployment of resources of land, labour and capital so to produce food and a range of other products which mankind needs or requires. Using the term "efficient" in the sense "effective". agriculture has obviously been efficient over the centuries for it has resulted in the production of sufficient food to support population growth in the world as a whole and a small but discernible increase in average living standards. Whether agriculture is efficient in the sense of making best use of the resources it deploys is perhaps another question, one to which this study of biological efficiency in agriculture addresses itself.

The major tool employed by the authors in the analysis is that of estimating ratios of the outputs of agricultures per unit time to a number of different inputs, these ratios being termed efficiencies. It is recognized that such single estimates can only apply to specific and highly defined situations, and that the approach can provide little information about the optimization of inputs into agricultural systems. As such, the book is essentially descriptive rather than analytical. It describes crop and animal production systems in many parts of the world in terms of a series of ostensibly simple ratios such as yield per hectare, output per unit of human labour, and yield per unit of fertilizer or water applied and of support energy provided. Annual yields are expressed in terms of dry weight or of energy-yielding constituents edible by man or of protein edible by man. Little emphasis is given to the complexity of the interrelationships between the input terms, that is to response analysis in what must be regarded as a multidimensional system.

A descriptive approach such as that adopted might, nonetheless, have considerable comparative value, so enabling judgements of the relative merits of different crops to be made. The fact that the ratios apply to highly specific contexts of soil, climate, economic and social circumstance, however, makes this impossible. The data assembled in the many tables are interesting as statements about what occurs in farming in different parts of the world. They also have value in predicating a series of other questions in the minds of readers about how to judge the merits of a cropping or stocking system in a particular agricultural setting.

It is wrong to criticize a book because it is about the wrong subject. Nevertheless, a conclusion emerges from this volume which touches on the wider issues, namely that it is important to decrease the input osupport energy into agriculture throughout the world without reducing total food production. Distinctions armade between those uses of support energin terms of fertilizers and agrochemical which augment the efficiency with which incident solar radiation is used to produc food and those in which machines simply substitute for manpower. This is a reaquestion which could well have been developed from a closer analysis of the large amount of descriptive material presented. Perhaps such an analysis is already in the minds of the authors.

Sir Kenneth Blaxter is Director of the Rower Research Institute, Bucksburn, Aberdeen.

L'animal-machine

J.E.R. Staddon

Quantitative Ethology: The State Space Approach. By David McFarland and Alasdair Houston. Pp.204. ISBN 0-273-08417-8. (Pitman: 1981.) £17.50-\$24-95

Most ethologists accept the idea tha animal behaviour is to be explained in purely mechanistic way. What could be more natural, then, but to turn to engineering, the science of mechanism, for the theoretical analysis of behaviour? So is has seemed to David McFarland and his group at Oxford who for the past 15 year or so have pursued the engineering approach with unequalled thoroughness and sophistication. This book is a summar of their work and the work of others in the same tradition.

The work of the Oxford group has gon through two phases. The initial phase was McFarland's application of linear system analysis to a variety of quantitative motivational problems in which the level of some activity — rate of drinking, or attack or pressing a lever in a Skinner box, of feather fluffing — was measured as a function of a single independent variable usually time. This work resulted in Feedback Mechanisms in Anima Behaviour, published by Academic Pres in 1971.

Simple linear systems analysis represent the state of a system by a single number but this is obviously an arbitrar! restriction. It is much more natural to represent the motivational state of an animal by a point in N-dimensional space. This is termed a state-space analysis by engineers. It also corresponds to a mode o representation commonly used by economists. In the motivational case, each axi

might represent the level of some crucial physiological variable; in the economic case, each axis gives the amount consumed of a commodity. In both instances, the benefit to the individual associated with points in the space is represented by a set of equal-benefit contours. Ouantitative Ethology is largely devoted to descriptions of static and dynamic applications of the state-space approach, the second phase of the Oxford group's programme. The book provides a useful catalogue of methods of analysis and examples of applications. Techniques discussed include the method of Lagrange multipliers (a standard tool for economists), Pontryagin's maximum principle (an approach to dynamic optimization), classical control systems theory, and measurement theory (a discussion of the combination rules describing the collective effect of stimuli and other causal factors on behaviour).

This book differs from McFarland's earlier one in another respect: its emphasis on adaptive function. The formal similarity of the economic and engineering approaches allows the authors to move easily from mechanistic models to optimality models, from an engineering approach where the animal is treated as a control mechanism that seeks to maintain the point representing its internal state within an "acceptable" region, to an economic approach where the organism is assumed to maximize its fitness. In their discussion of decision rules the authors show that they are well aware of the distinction between the limited means animals use to achieve optimal behaviour, and the optimality analyses that define optimal behaviour. Yet the formal similarity between the economic and engineering versions of state-space analysis suggests that further work is necessary to separate the ideal from the means the animal uses to achieve it.

Depending on their definition of "ethology", some will quarrel with the title of the book. If you believe that the distinction between ethology and animal psychology is that the former deals with the ways in which animal species differ from one another, whereas the latter is interested in their similarities, then you will find McFarland and Houston's book closer to psychology than ethology. If you feel that the important questions in ethology are social, or involve ecology neurophysiology, then the book is not for you. On the other hand, if you consider that our best hope for understanding animal behaviour is to begin with the large and potentially quantifiable processes of motivation and steady-state operant behaviour, then Quantitative Ethology presents the clearest exposition to date of the work of the Oxford group on these topics.

J.E.R. Staddon is a Professor in the Departments of Psychology and Zoology at Duke University.

Fruits of Australian botany

David W. Goodall

Flora of Australia. Vol.1, Introduction. Pp.200, ISBN hbk 0-642-06652-3; ISBN pbk 0-642-06653-1. (Australian Government Publishing Service, Canberra: 1981.) Hbk \$A15.50; pbk \$A10.50. The Vegetation of Australia. By Noel C.W. Beadle. Pp.690. ISBN 0-521-24195-2. (Cambridge University Press: 1981.) £50, \$120. Australian Vegetation. Edited by R.H. Groves. Pp.449. ISBN hbk 0-521-23436-0; ISBN pbk 0-521-29950-0 (Cambridge University Press: 1981.) Hbk £27.50, \$64.50; pbk available in Australia only. The Biology of Australian Plants. Edited by J.S. Pate and A.J. McComb. Pp.412. ISBN 0-85564-194-0. (University of Western Australia Press: 1981.) \$A25.

No flora of the whole of Australia has been compiled since George Bentham's Flora Australiansis, published from Kew between 1863 and 1878. It is still a standard reference work, despite the enormous amount of taxonomic research undertaken during the intervening century (twice as many species of higher plants are now known in Australia as were recorded by Bentham). State and regional floras have been written but, for important parts of the continent, there has been nothing to replace Bentham — out of date as it is.

Accordingly, it was a major event for Australian botany when, after 20 years' gestation, arrangements were finally completed in 1979 for the publication of a new flora of Australia, of which the first volume is reviewed here. It is planned that Flora of Australia will cover the vascular plants in 48 volumes, with an unspecified number of subsequent volumes to deal with the lower plants; attention is at present concentrated on the flowering plants, and practically every angiosperm taxonomist working in Australia will be involved in one or other of the volumes.

The present book is explicitly an introduction to the series. The main elements are an excellent chapter by B.A. Barlow on the origin and evolution of the vascular flora; an outline of the system of classification used, in which A. Kanio compares the recent systems of Takhtajan, Dahlgren, Thorne and Cronquist with more traditional ones; and a key to angiosperm families by H.T. Clifford. The last is based primarily on experience in Queensland, and comments are invited as to how satisfactory it proves on the continental scale. Certainly, this section of the volume is likely to be in frequent use by nonspecialists.

A flora is judged, however, not by its introductory material but by the quality of the species descriptions and keys. I have had the opportunity of seeing proofs of another volume in the series, and it is clear that high standards are being set and achieved. Descriptions are clear, including

notes on ecology and geographical distribution (numerous maps are included). The original description and type specimen are identified, and some representative specimens in Australian herbaria are listed.

It is clear that this series will be in constant demand and use wherever serious taxonomic work is in progress. It will be a necessity for all botanical libraries in Australia, and all taxonomic libraries throughout the world.

Two of the other books covered in this review, those of Professor Beadle and Dr Groves, have much in common; both are concerned with vegetation types, have very similar titles and (surprisingly) come from the same publisher. The first, however, is almost entirely one man's work, the second has separate authors for each chapter. Both, but particularly the first, are well illustrated with numerous photographs. Recurring themes in the two volumes are the importance of nutrient status -Australia is a very old landmass, much of which is deficient in various nutrients, particularly phosphorus - and fire as a regular component of the environment to which Australian vegetation has become adapted.
